(54) Cable television system.

(5) A cable television system and method in which each subscriber's converter is located outside the subscriber's premises in an external control unit ("ECU") which also includes several other subscribers' converters. The ECU includes common signal processing circuitry for controlling all the converters in the ECU. In addition to television signals, the cable network transmits control and data signals in both directions between the ECU and the head end of the system and between the ECU and each subscriber. Each subscriber supplies a portion of the power required by the associated ECU. Multiple television channels can be supplied to each subscriber via a single drop cable connecting the subscriber to the ECU.

CABLE TELEVISION SYSTEM

Background of the Invention

This invention relates to cable television systems, and more particularly to cable television systems in which the converter for converting portions of the television signal on the cable network to the television signal which is applied to the subscriber's television receiver is located outside the subscriber's premises.

There is increasing interest in cable television systems in which the converter for converting the portion of the cable television signal which the subscriber desires to receive to a signal suitable for application to the subscriber's television set is located outside the subscriber's premises, for example, on or adjacent to a neighboring utility or telephone pole. This is of interest because it reduces the risk of unauthorized tampering with the converter, accidental or intentional misappropriation of or damage to the converter, and the like.

On the other hand, locating the converter outside the subscriber's premises increases the complexity and cost of the system because apparatus must then be included in the system to enable the subscriber to remotely control the converter. This consideration has tended to discourage the develop-

ment of cable television systems with off-premises converters.

It is therefore an object of this invention to improve, simplify and reduce the cost of cable television systems with off-premises converters.

Summary of the Invention

This and other objects of the invention are accomplished in accordance with the principles of the invention by providing a cable television system and method in which the off-premises converters of several adjacent subscribers are at least partially controlled by common signal processing circuitry associated with those converters. common signal processing circuitry and all the associated converters are preferably located in a common facility, for example, a housing mounted on or adjacent to a utility pole neighboring the premises of the associated subscribers. This apparatus is referred to herein as an external control unit or "ECU". The ECU preferably includes only a single tap for each network cable serving the ECU. The signals derived from this tap are distributed appropriately to the components of the ECU. A drop cable extends from the ECU to each subscriber's premises.

Inside the subscriber's premises the drop cable is connected to a subscriber processing unit or "SPU" which is typically located adjacent to the subscriber's television receiver. The SPU applies the television signal on the drop cable to the television receiver and also applies subscriber-originated control signals to the drop cable for transmission back to the ECU. Other devices located in the subscriber's premises, such as burglar, fire and other alarm or monitoring equipment capable of applying control signals to the drop cable for transmission

back to the ECU, can also be connected to the drop cable.

The ECU processes the control signals originated by all of the associated subscribers to satisfy, if appropriate, the service requests indicated by those control signals. In particular, the common signal processing circuitry in the ECU is used as extensively as possible to process the subscriber-originated control signals to minimize the amount of separate ECU circuitry which must be provided for each subscriber.

The ECU is also capable of receiving and responding to control signals from the so-called "head end" of the cable network. For example, these control signals may include channel authorization data identifying which channels on the cable network a particular subscriber is authorized to receive and view. These head-end-originated control signals are preferably transmitted via the cable network, and the common signal processing circuitry in each ECU is again used as extensively as possible to process these signals. Because each ECU typically serves several subscribers, all of those subscribers can be serviced from the head end by control signals addressed to the ECU rather than to each subscriber individually. This greatly facilitates control of the system from the head end.

Further features of the invention, its nature and various advantages will be more apparent from the accompanying drawing and the following detailed description of the invention.

Brief Description of the Drawing

Detailed Description of the Invention

I. Overview of the System

As shown in Figure 1, an illustrative embodiment of the cable television system 10 of this invention includes head end apparatus 12; cable network 14; a plurality of external control units ECU1, ECU2, etc., connected to cable network 14 at locations which are typically remote from one another and from head end 12; and a plurality of subscriber premises SUB1, SUB2, etc., each of which is connected to an associated ECU by a drop cable DROP1, DROP2, etc. In the particular embodiment shown in the drawing, each ECU can be connected to as many as six subscribers, but this number is arbitrary and the maximum number of subscribers per ECU can be larger or smaller than six as desired.

Head end 12 typically includes one or more sources of television signal information such as conventional satellite antenna 20. Conventional satellite receiver 22 separates the television signal information received via antenna 20 into a plurality of base band television signals, each of which represents one base band television channel.

conventional modulator 24 modulates each of these television signals so that each base band channel is shifted to a predetermined frequency or "physical" cable channel for distribution via cable network 14. Additional base band television and other signals (e.g., television signals from studio cameras or video recorders, FM audio signals, etc.) may also be applied to modulator 24 via leads 26, 28, etc., and shifted to predetermined physical cable channels by the modulator.

All of the output signals of modulator 24 are applied to conventional combiner 30 which combines them for application to cable network 14 via conventional combiner 32. Combiner 32 also adds control and data signals to the signal applied to cable network 14. These control and data signals may be of two types: (1) a so-called "forward data" signal which represents information generated at head end 12 for controlling the ECUs in the network, and (2) a forward high data rate channel ("HDRC") signal which is typically included in the FM band and which allows the cable network to be used for such purposes as distributing non-television signal data (e.g., general purpose computer programs and data) to the subscribers. Because the forward HDRC signal is typically included in the FM band, the term "FM audio signal" as used herein includes the forward HDRC signal if such a signal is employed in the system.

In addition to adding forward data and forward HDRC signals to the signal applied to cable network 14, combiner 32 also conducts so-called "reverse data" signals in the opposite direction from cable network 14 to modem 34. The reverse data signals are control signals generated by the ECUs as described below for transmission to head end 12 for use in controlling the cable television network. In

the illustrative embodiment shown and described herein, four channels are available for reverse data
communication. Modem 34 converts (modulates) forward
data signals produced by central control computer
("CCC") 36 to signals suitable for transmission via
cable network 14. Modem 34 also converts (demodulates) reverse data signals received from cable network 14 to signals suitable for processing by central control computer 36.

Y

combiner 32 also extracts from the signal on cable network 14 a reverse HDRC signal which allows the cable network to be used for such purposes as transmitting non-television signal data (e.g., fire and burglary alarm signals) from the subscribers to a central location such as head end 12. The reverse HDRC signal is typically in a frequency band (e.g., 25 MHz) which is independent from all other frequency bands employed in the system. The use of a reverse HDRC frequency band in the present invention enables direct two-way communication between the head end and the subscribers, and minimizes noise and other signal degradation problems affecting other communication signals on the CATV cable and inherent in conventional two-way CATV systems.

Each ECU includes a conventional tap off device 50 for applying the signals which appear on cable network 14 to the circuitry of the ECU and for applying to cable network 14 the reverse data originating at the ECU and the reverse HDRC signals originating at the associated subscribers. Each ECU is typically located outside the premises of the subscribers served by the ECU. Typically, all the circuitry of the ECU is located in a common housing which may be adapted for mounting on a utility pole or other suitable structure adjacent to the premises of the subscribers served by the ECU.

Tap off device 50 is connected to conventional splitter-combiner network 52. Splitter-combiner network 52 distributes the signals received from cable network 14 to a plurality of subscriber units SU1, SU2, etc. within the ECU, each of which is associated with a respective one of the subscribers served by the ECU. Although each SU includes additional apparatus described in detail below, for the moment it will be sufficient to think of each SU as a digitally controlled converter for performing the television signal frequency conversion function performed by the converter located adjacent the subscriber's television receiver in conventional cable network systems.

splitter-combiner network 52 also distributes the signals received from cable network 14 to analog unit 54, described in greater detail below. In general, analog unit 54 separates the FM audio and forward data signals from the other signals received from cable network 14. Analog unit 54 applies the FM audio signal to each SU for transmission to the subscribers. Analog unit 54 also demodulates the forward data signal and applies the resulting data signal to digital unit 55. Analog unit 54 applies reverse HDRC signals received from the SUs to splitter-combiner network 52, and splitter-combiner network 52 applies those reverse HDRC signals to tap off device 50 and thereby to cable network 14.

Splitter-combiner network 52 also applies reverse data signals from communication unit 56 to tap off device 50. In addition, if a so-called "slave" ECU (not shown in Figure 1) is associated with "master" ECU1 as described in detail below, splitter-combiner network 52 conveys signals in both directions via lead 58 between tap off device 50 and the splitter-combiner network of the slave ECU.

As mentioned above, each SU receives the entire cable network signal from splitter-combiner network 52. In response to control signals received from digital unit 55, each SU (1) selects from the cable network signal the portion of that signal representing the television channel which the associated subscriber wishes to view, and (2) converts that signal portion to a television signal on a predetermined channel (e.g., channel 3) to which the associated subscriber's television receiver 90 is tuned. This television signal is applied to the SU's associated drop cable DROP1, DROP2, etc., which runs from the SU to the associated subscriber's premises SUB1, SUB2, etc. Each SU also receives the FM audio signal from analog unit 54 and combines that signal with the television signal applied to the associated subscriber's drop cable.

The ECU communicates via each SU with the associated subscriber's apparatus (in particular, the SPU of the associated subscriber) by means of so-called very low frequency ("VLF") data signals on the associated drop cable. Also, when a subscriber operates his or her SPU to make a television channel selection, the SPU applies to the associated drop cable for transmission to the ECU VLF data signals representative of the desired channel selection. Each SU conveys these VLF data signals in both directions between the associated subscriber drop cable and communication unit 56 which includes a modem for conveying these VLF data signals to and from digital unit 55. Each SU also conveys reverse HDRC signals from the associated subscriber drop cable to analog unit 54.

The power required to operate each ECU is supplied by the subscribers served by that ECU. Each subscriber has an SPU which applies an alternating current ("AC") power signal to the associated

drop cable. The associated SU conveys that power signal to common power unit 60 in the ECU. Common power unit 60 combines all of the applied power signals and derives from the combined signal the currents and voltages needed to power the various components of the ECU. In this way, all of the subscribers served by the ECU share the power requirements of the ECU. In the event of a general AC power failure, common power unit 60 applies a control signal to digital unit 55 which causes the digital unit to shut down in such a way that important data is not lost.

Digital unit 55 controls the operation of the ECU. Digital unit 55 receives and processes forward data applied to the digital unit via analog unit 54. Digital unit 55 also generates reverse data and applies that data to communication unit 56 for transmission to head end 12. Digital unit 55 receives and processes demodulated VLF signals applied to the digital unit via communication unit 56 from all of the SUs in the ECU. Digital unit 55 also generates other signals for transmission back to the subscribers via communication unit 56 and the SUs. Digital unit 55 also controls various functions of the SUs. For example, when a subscriber wishes to view a particular television channel, digital unit 55 receives VLF signals generated by the subscriber indicating the desired channel selection, determines whether or not the subscriber is authorized to receive that channel based upon channel authorization data previously provided by head end 12, and, if the subscriber is authorized to receive the desired channel, controls the subscriber's SU to cause it to apply the desired channel signal to the subscriber's drop cable.

Each subscriber has at least one SPU, at least one conventional television receiver 90 con-

nected to the SPU, and (optionally) a conventional remote control unit ("RCU") for remotely controlling the SPU by infrared or other signals. The SPU is connected to the drop cable and applies the received drop cable signal to the associated television receiver 90. The received drop cable signal may also be applied to the subscriber's (optional) FM audio receiver equipment (not shown) and to the subscriber's (optional) forward HDRC utilization equipment (also not shown). The SPU has a conventional keypad (not shown in Figure 1) for allowing the subscriber to enter data such as the number of the television channel the subscriber wishes to receive. Alternatively, this data can be entered via the subscriber's RCU. The SPU converts data entered by the subscriber to VLF data signals which are transmitted to the associated ECU via the subscriber's drop cable. The SPU also typically has data display elements such as seven-segment light emitting diode ("LED") displays. These displays can be controlled by VLF data sent to the SPU from the associated ECU. The SPU also applies the reverse HDRC signal originated by the subscriber to the associated drop cable.

The following Table A summarizes the allocation of carrier signal frequencies in the illustrative embodiment of the invention shown and described herein:

TABLE A

	Type of Signal	Approximate Frequency
1.	AC Power	60 Hz
2.	VLF Data (ECU to SPU)	430 KHz
3.	VLF Data (SPU to ECU)	468 KHz
4.	Reverse Data	
	a. Channel 0	19.125 MHz
	b. Channel 1	19.375 MHz
	c. Channel 2	19.625 MHz
	d. Channel 3	19.875 MHz
5.	Reverse HDRC Data	25 MHz
6.	Television	50-88 MHz 108-450 MHz
7.	FM Audio (Includes Forward HDRC Data)	88-108 MHz
8.	Forward Data	104 MHz

It will be understood that the frequencies shown in Table A are merely illustrative and that other frequencies can be employed if desired. For convenience herein, the television and FM audio signals on cable network 14 (items 6 and 7 in Table A, above) are sometimes hereafter referred to collectively as CATV signals.

Although cable network 14 has only a single feeder cable in the embodiment shown in Figure 1,
two feeder cables can be employed if desired to increase the number of television channels available
for distribution to subscribers. For example, if
two cables were provided, elements such as 24, 30,
32, 50, and 52 would be substantially duplicated to
serve the second cable. Each SU would receive input
CATV signals from each cable. To select between the

two cables, each SU would also include a switch controlled by digital unit 55 for switching between the two applied cable signals. This is discussed in greater detail below in relation to the SUs. In a multi-cable system, the FM audio, reverse HDRC, forward data, and reverse data signals are preferably transmitted by only one cable, designated the primary cable, thereby allowing some simplification of the apparatus associated with the other cable or cables. Thus, elements such as 34, 36, 54, 55, 56, and 60 do not have to be duplicated or even significantly altered to provide a multi-cable system.

It is also possible for each subscriber to have more than one television receiver 90. The additional television receiver or receivers can be attached to one SPU, in which case all of the television receivers receive the same television signal. Alternatively, the additional television receiver or receivers can be served by a second SPU to enable the subscriber to simultaneously select and receive two different television channels. If a subscriber has two SPUs, both of the SPUs can be connected to a single drop cable. In such a case, one SPU will be configured as a "master" SPU, and the other will be configured as a "slave" SPU. At the ECU, a subscriber with a master and slave SPU is served by two SUs. Each SU is associated with a different SPU. The signals from both SUs are multiplexed onto the single drop cable. The television signal from the first or "primary" SU is converted by the SU to, and applied to the drop cable as, a first or lower drop cable channel. The television signal from the other or "secondary" SU is converted to, and applied to the drop cable as, a second or higher drop cable channel. The television receiver associated with each SPU is tuned to a respective one of the two drop cable channels.

Thus, each subscriber has at least one primary SU in the ECU associated with a master SPU. If a subscriber has two SPUs, that subscriber may also have a secondary SU in the ECU associated with the slave SPU. In any event, the total number of SUs which can be included in an ECU in the particular embodiment shown and described herein is six.

at the location of an ECU which is operating at capacity, then a second or "slave" ECU containing six more SUs can be connected to the splitter-combiner network 52 of the "master" ECU via lead 58 as mentioned above. In this way, additional subscriber service can be provided without the necessity of cutting into the cable network 14 to insert an additional tap 50.

II. Subscriber Unit

Figure 2 shows a typical subscriber unit SUl in greater detail. The cable network signal from splitter-combiner network 52 (Figure 1) is applied to conventional converter tuner 100 via the INPUT terminal and optional switching device 102. If the system had two cables rather than one as shown in Figure 1, each SU would have two INPUT terminals, each connected to a respective one of the two cables. Switching device 102, which can include a conventional RF switching relay such as part number G4Y-152P available from Tateishi Electric Co. ("Omron") of Tokyo, Japan, would then be used to apply one or the other of the two cable signals to converter tuner 100. Switching device 102 would be controlled to select signals from one or the other CATV feeder cable by a conventional transistor switch (part of switching device 102) responsive to the state of the Q3 output on pin 7 of conventional addressable latch 140.

Converter tuner 100, together with conventional frequency synthesizer 104 and the circuits including crystal 106, capacitors 108, 110, 112, 114, 116, 118, 120, resistors 122, 124, 126, 128, and transistors 130 and 132, selects the portion of the cable television signal which the associated subscriber wishes to receive, converts that signal portion to a television signal on the channel to which the subscriber's television receiver 90 is tuned, and applies that signal to the DROP CABLE output terminal of the SU via conventional FM adder device 180, directional coupler 182, and capacitor 184. In one embodiment, converter tuner 100 may be part number CVA 213A (channel 3) or CVA 215A (channel 5) available from Toshiba Corporation of Tokyo, Japan (hereinafter "Toshiba"), or an equivalent device to convert the CATV signals to the same or other channels or frequencies. Frequency synthesizer 104 may be Toshiba part number TD6352P or an equivalent device.

The converter circuitry operates as follows. Via its DATA input lead, frequency synthesizer 104 receives a ten-bit main channel conversion coefficient ("MCCC") and a five-bit "swallow" conversion coefficient ("SCC"). The bits of these two coefficients, which are sometimes collectively referred to as the main and swallow ("MS") coefficients, are shifted into frequency synthesizer 104 at the clock rate established by its CLOCK input. When all the bits of the MS coefficients have been shifted into frequency synthesizer 104, they are latched into the synthesizer in response to a signal applied to the LOAD input terminal. Frequency synthesizer 104 then uses the MS coefficients in a known manner to (1) scale down the frequency of the voltage controlled LOCAL OSCILLATOR ("LOC. OSC.") output signal of converter tuner 100, (2) perform a phase

detection comparison between the scaled down LOC.

OSC. signal frequency and the reference OSCILLATOR

("OSC.") signal frequency provided in part by crystal

106, and (3) produce an error signal at the PHASE

DETECTOR OUTPUT ("P/D OUT") terminal. The error

signal produced by frequency synthesizer 104 is used
to control the voltage controlled oscillator in converter tuner 100 to cause that oscillator to produce
the demodulation signal frequency needed to convert
the desired cable channel to the channel to which
the subscriber's television receiver 90 is tuned.

Addressable latch 140, which may be Toshiba part number TC40H259 or an equivalent device, receives control and data signals from digital unit 55, stores that data, and outputs it to frequency synthesizer 104. In particular, addressable latch 140 receives data via its DATA input lead and processes that data in accordance with the function control signals applied to its A, B, and C input leads. The addressable latch in a particular SU is selected and thereby enabled by an appropriate signal applied to the NOT ENABLE ("NEA") input terminal of the addressable latch to be selected. (In general, the logical polarity of signals and signal names appearing in the drawings will be ignored in this specification. Thus, for example, whereas the signal at pin 14 of addressable latch 140 is actually an inverse enable signal, that signal is simply referred to in this specification by its functional name "NEA" without regard for its logical polarity.) Resistors 142-147 are pull-up resistors conventionally associated with selected inputs and outputs of addressable latch 140.

Addressable latch 140 also monitors whether or not the associated subscriber is supplying his or her share of the AC power needed to operate the ECU. This function is performed in response to the

signal applied to the CLEAR ("CL") input terminal of addressable latch 140. If the associated subscriber is not providing AC power to the ECU via the subscriber's drop cable, the Q4 output signal of addressable latch 140 controls the circuit including resistors 150-152, transistors 153-155, diode 156, inductor 158, and capacitor 159 to shut off power to associated converter tuner 100. This prevents any subscriber who is not supplying AC power to the ECU from receiving television signals from the ECU. The Q5 output signal of addressable latch 140 also indicates whether or not the associated subscriber is supplying AC power. This Q5 output signal is applied to the POWER DETECT output terminal of the SU for use by digital unit 55.

Each primary SU such as SU1 has a power section which includes filtering inductor 160, diodes 161-163, capacitors 164-167, and resistors 168-169. Inductor 160 blocks VLF and CATV signals. Diodes 161 and 162 respectively produce half-wave rectified power signals ("+" and "-") from a 60 volt or less AC power signal on the associated drop cable. The + and - signals are respectively connected to and summed with other + and - power signals from other subscribers and SUs (i.e., SU2-SU6) in the ECU. The summed power signals then are applied to common power unit 60 which is described in detail below. Circuit elements 163 and 167-169 constitute another halfwave rectifier circuit which produces a DC output signal (which is clamped to approximately +5V by diode 157) as long as the associated subscriber is supplying AC power via the drop cable. This DC output signal is applied to the CL input terminal of addressable latch 140 via voltage dividing resistors 170-171 for the purpose described above.

If a secondary SU (e.g., SU2) is associated with SU1 to enable the subscriber to select and

receive two multiplexed channels via the drop cable, then the DC output signal produced by elements 163 and 167-169 is also applied to the secondary SU via resistor 172 in the primary SU and jumper 173 in the secondary SU. Jumper 173 is a completed connection only in the secondary SU. Power supply elements 160-169 are omitted from the secondary SU, as is capacitor 184. Also in the secondary SU, the terminal corresponding to the DROP CABLE terminal in Figure 2 is connected to the FM INPUT AND REVERSE HDRC OUTPUT terminal of the associated primary SU. Thus, the secondary SU selects one television channel, adds the FM signal to the first television channel signal, and applies the resulting signal to the FM INPUT AND REVERSE HDRC OUTPUT terminal of the associated primary SU. The primary SU selects the second television channel, adds that signal to the signal received from the secondary SU, and applies the resulting signal to the subscriber's drop cable. In this way each subscriber can receive as many as two television channels multiplexed on a single drop cable. As mentioned above, each of the subscriber's television receivers is tuned to view one or the other of the two channels on the drop cable. only other differences between the primary and secondary SUs are (1) the use of different local oscillator frequencies so that the primary and secondary SUs place the selected cable channels on different drop cable channels, and (2) the omission in the secondary SU of what would otherwise be a redundant VLF input/output.

The remaining elements in the SU are (1) a power filtering circuit including inductor 190 to block high-frequency signals from entering the +27V power line, and capacitor 192 and resistor 194 to remove high-frequency ripple from the +27V power

line, and (2) capacitor 196 which is connected between the VLF input/output lead and ground. Directional coupler 182 conveys VLF signals in both directions between the drop cable and the VLF input/output terminal.

III. Analog Unit

As shown in Figure 3, analog unit 54 includes bandpass filter 200 for extracting the FM audio (approximately 88-108 MHz) and forward data (104 MHz plus or minus 100 KHz) signals from the CABLE SIGNAL. The FM signal is applied to each of the FM OUTPUT AND REVERSE HDRC INPUT terminals of analog unit 54 via input/output coupling network 202. Each FM OUTPUT AND REVERSE INPUT HDRC terminal of analog unit 54 is connected to the FM INPUT AND REVERSE HDRC OUTPUT terminal of a respective one of the SUs.

Input/output coupling network 202, bandpass filter 204, and lowpass filter 206 convey reverse HDRC signals (25 MHz plus or minus .5 MHz) from the FM OUTPUT AND REVERSE HDRC INPUT terminals to the CABLE SIGNAL terminal. Thus, filters 204 and 206 allow reverse HDRC signals to pass from subscriber premises SUB1, SUB2, etc. (Figure 1) through the ECU and directly to cable network 14, thereby providing a data signal path for direct communication via cable network 14 between the subscribers and head end 12. However, filters 204 and 206 block other signals from directly passing from the subscribers and drop cables to cable network 14. In particular, filters 204 and 206 prevent signals, such as citizen band and other two-way radio signals, from entering cable network 14 and interfering with or degrading the reverse data signals sent from the ECUs to head end 12. In contrast, in a conventional two-way cable television system, such interfering signals typically are picked up at various poorly or loosely connected or dirty or corroded drop cable connections and cracked cable shields in the CATV system. The use of an HDRC channel and elements 204 and 206 in the CATV system of the present invention thus allows for reliable, high-speed, direct two-way communication between subscribers and head end 12 by isolating cable network 14, and the reverse data transmitted thereon, from interfering signals picked up by numerous drop cable connections.

Conventional bandpass filter 210 extracts the forward data signal from the output signal of bandpass filter 200. The forward data output signal of bandpass filter 210 is applied to mixer 212 for mixing with the 108.5 MHz output signal of local oscillator 214. The resulting 4.5 MHz output signal is amplified by conventional intermediate frequency amplifier 216 and applied to conventional detector 220. Detector 220 converts the frequency-modulated ("FM") forward data signal to a base band forward data signal which is applied to the FORWARD DATA OUTPUT terminal of analog unit 54 for application to digital unit 55.

IV. Communication Unit

Figure 4 shows communication unit 56 in greater detail. Communication unit 56 is controlled by digital unit 55 and facilitates communication of (1) reverse data from the ECU to the CCC of head end 12, and (2) VLF data to and from the ECU and each associated subscriber's SPU.

For communicating information from the ECU to head end 12, communication unit 56 includes reverse channel selector 300, conventional modulator 330, and conventional bandpass filter 332. Channel

selector 300, on command from digital unit 55, selects any one of four available reverse channels for transmission of ECU reverse data to head end 12. A two-bit reverse channel selection signal ("REV. CH. A" and "REV. CH. B") is applied from digital unit 55 to conventional binary decoder 302. Depending on the bit combination present on the A and B inputs of decoder 302 (i.e., 00, 01, 10, or 11), one of the four outputs of decoder 302 will be low and all other outputs will be high. The outputs of decoder 302, each of which is connected to a respective one of four crystal-controlled oscillators 304. 306, 308, and 310, in turn cause one of the four oscillators to be operative. Each oscillator 304, 306, 308, and 310 is tuned to oscillate at a different frequency corresponding to one of the frequencies of the four channels available for reverse data communication. In one embodiment, oscillators 304, 306, 308, and 310 operate at 19.125 MHz, 19.375 MHz, 19.625 MHz, and 19.875 MHz, respectively. It will, of course, be appreciated that other frequencies and a different number of reverse channels can be used if desired.

The output of the particular oscillator selected by decoder 302 is applied to modulator 330 as a carrier frequency for modulation by the reverse data to be transmitted to head end 12. Modulator 330 can be any conventional modulator for modulating digital signals onto an analog carrier. In a preferred embodiment, modulator 330 is a binary phase-shift keyed ("BPSK") modulator, such as part number MC 1496 available from Motorola Corporation of Phoenix, Arizona (hereinafter "Motorola"). Data is modulated for transmission on each reverse channel at a data rate of 50 Kbps.

Channel selector 300 also includes conventional logic circuit 305 (comprised, for example, of

3

conventional NOR and NAND gates) for receiving and enabling the transmission of digital reverse data from digital unit 55 to head end 12, and for receiving a request-to-send ("RTS") signal from and providing a clear-to-send ("CTS") signal to digital unit 55. If digital unit 55 is not sending data to head end 12, digital unit 55 maintains the RTS lead to logic circuit 305 in a logical "0" state. causes logic circuit 305 to apply a signal to transistor 309 through current-limiting resistor 307, thus shorting the output of oscillators 304, 306, 308, and 310 to ground and preventing the application of carrier to modulator 330. In addition, logic circuit 305 (1) maintains the CTS lead in a logical "1" state, thus signaling to digital unit 55 that it is not clear to send data, and (2) disables transmission of data signals to modulator 330. digital unit 55 desires to send data to head end 12, it raises the RTS lead. This causes logic circuit 305, after a short delay, to (1) remove the signal from transistor 309 to allow a carrier signal to be applied to modulator 330, (2) present a logical "0" state on the CTS lead to signal digital unit 55 that it is clear to send data, and (3) enable the passage of data signals to modulator 330. Digital unit 55 may transmit data only while CTS is in a logical "0" state.

Modulator 330 modulates the reverse data presented at its data input line onto the carrier signal presented at its carrier input line. The output of modulator 330 is a modulated signal having a selected one of four carrier frequencies which is applied to bandpass filter 332. Bandpass filter 332 has a 1 MHz passband centered at 19.5 MHz. The output of bandpass filter 332 is reverse channel output, which is applied to splitter-combiner network

52 (Figure 1) for transmission via cable network 14 to head end 12.

For enabling communications between the ECU and each associated subscriber SUB1, SUB2 ... etc., communication unit 56 includes bi-directional multiplexer 350 for connecting a first input/output line to any one of a plurality of second input/output lines as a function of a binary code appearing on subscriber address lines A, B, and C. Subscriber address lines A, B, and C are connected to digital unit 55 to enable digital unit 55 to selectively connect any one of the plurality of second input/output lines to the first input/output line. In a preferred embodiment, multiplexer 350 is a 1-to-8 multiplexer, such as Toshiba part number TC4051BP, having 8 second input/output lines, only 6 of which are used (one for each of up to six SUs). Each of the second input/output lines is connected to the VLF input/output terminal of a respective one of subscriber units SU1, SU2 ... etc. (see Figure 2). By presenting different code combinations on address lines A, B, and C (i.e., 000, 001, 010, 011, 100, or 101), digital unit 55 can select a particular drop cable to enable a particular subscriber to communicate with the ECU.

For receiving communications from subscribers, the first input/output line of multiplexer 350 is connected through DC-blocking capacitor 336 to the input of very low frequency ("VLF") demodulator 340. VLF demodulator 340 receives VLF-modulated analog signals transmitted from the SPUs at a data rate of 1200 bps (or any other convenient rate) and demodulates those signals into serial digital data for processing by digital unit 55. In one embodiment, the VLF signals received from the SPUs are

4

on/off amplitude-shift keyed ("ASK") modulated signals having a carrier frequency of 468 KHz. A logical "1" (mark) is represented by 100% carrier, and a logical "0" (space) is represented by 0% carrier. Demodulator 340 includes a conventional parallel tuned LC circuit 342 tuned to produce an output in response to the receipt at its input of a signal having a frequency of 468 KHz. The output of circuit 342 is applied to surface acoustic wave ("saw") filter 344 also tuned to 468 KHz. The output of saw filter 344 in turn is connected to conventional amplifier 346 which produces a mark and space data output in response to the presence and absence of carrier. This data output is applied to digital unit 55 for processing as data received from the SPUs.

For communication from the ECU to the SPUs, data from digital unit 55 is applied to the data input connection of VLF modulator 320. In one embodiment, VLF modulator 320 modulates digital data signals at a data rate of 1200 bps (or any other convenient rate) from digital unit 55 into an on/off ASK analog VLF signal having a carrier frequency of 430 KHz. Data from digital unit 55 turns on and off transistor 327 (via current-limiting resistor 328). Transistor 327 in turn controls on and off FET transistor switch 324 via resistors 325 and 326. 430 KHz carrier signal produced by conventional crystal-controlled oscillator 322 is applied to the base of transistor 360 which is connected in such a way that the carrier signal appears at the transistor's collector shifted 180° relative to the carrier signal appearing at the transistor's emitter. The collector carrier signal is switched on and off by transistor switch 324 in accordance with the VLF data to be transmitted to an SPU. This switched

carrier signal is applied to the first input/output line of multiplexer 350 via resistor 334 for transmission to one of the plurality of subscriber SPUs. The continuous carrier signal appearing at the emitter of transistor 360 is applied to all of the second input/output lines of multiplexer 350 via transistor 370 and resistors 381-386. In this way, there is constant 430 KHz carrier on all of the second input/output lines of multiplexer 350 except when the carrier on one of those lines is cancelled by the switched carrier from transistor switch 324.

V. Digital Unit

As shown in Figure 5, digital unit 55 has two major subparts. Those subparts are (1) signal processing portion 55a (shown in Figures 5a-5f), and (2) memory portion 55b (shown in Figures 5g-5i). These two portions of digital unit 55 are interconnected by means of the terminals represented by rectangles and numbered 01-40. For example, the terminal numbered 01 in Figure 5f is connected to the correspondingly numbered terminal in Figure 5g.

Digital unit 55 includes conventional universal synchronous or asynchronous receiver/transmitter ("USART") 400, such as part number 8274 available from Intel Corporation of Santa Clara, California (hereinafter "Intel"). USART 400 converts HDLC-formatted serial forward data received from head end 12 into parallel data for processing by the remainder of digital unit 55. USART 400 also converts parallel reverse data generated by other elements in digital unit 55 into HDLC-formatted serial data for transmission back to head end 12. The operation of USART 400 is augmented by gate array 402, shown in detail in Figures 5k-5s, which performs various functions such as converting non-return to zero inverted ("NRZI") forward data from

head end 12 on the FORWARD DATA lead to non-return to zero ("NRZ") "receive" data on the RXD lead. Gate array 402 also converts NRZ "transmit" data on the TXD lead to NRZI reverse data on the REVERSE DATA lead.

USART 400 and gate array 402 are also interconnected by INTERRUPT ("INT"), CLOCK ("CLK"), RXC, TXC, READ ("RD"), WRITE ("WR"), and RESET ("RES") leads. The INT signal is generated by USART 400, is inverted by gate array 402, and is applied to the INTO terminal of microprocessor 420. This signal is used to alert microprocessor 420 to the occurrence of an important event in USART 400 (e.g., the fact that a character has been received or transmitted via the FORWARD or REVERSE DATA leads). The CLK3 output signal of gate array 402 is derived from the CLKOUT output signal of microprocessor 420. In particular, the 6MHz CLKOUT signal is divided by two by gate array 402 to produce the 3MHz CLK3 output signal which is applied to USART 400. The RXC output signal of gate array 402 is a clock signal derived by gate array 402 from the NRZI forward data signal. The TXC input signal of gate array 402 is a clock signal produced by microprocessor 420 to control the rate at which reverse data is transmitted back to head end 12. The source of the RD and WR signals is microprocessor 420. These signals respectively cause other devices in digital unit 55 to output data so that microprocessor 420 can read it, or cause other devices in digital unit 55 to input data from microprocessor 420. The ultimate source of the RESET or RES signals is power detect circuit 480. The POWER DETECT input terminal of digital unit 55 is connected to the RESET output terminal of common power unit 60 (Figure 6). Power detect circuit 480 produces an output signal for

resetting microprocessor 420 when power is restored following a power outage. Microprocessor 420 responds to this RES input signal by producing a RESET output signal which is applied to the RESET input terminal of gate array 402. Gate array 402 applies an inverted RESET signal to USART 400, microcomputer 450, and hex inverting buffer 465.

Gate array 402 is shown in detail in
Figures 5k-5s. In Figure 5k, reference number 250
denotes a typical input buffer; reference number 252
denotes a typical AND gate; reference number 254
denotes a typical NAND gate; reference number 256
denotes a typical J-K flip-flop; reference number
258 denotes a typical D-type flip-flop; reference
number 260 denotes a typical OR gate; and reference
number 262 denotes a typical output buffer. In Figure 5s, reference number 264 denotes a typical
latch. The following Table B correlates the gate
array 102 pin numbers shown in Figure 5c with the
lead labels used in Figures 5K-5s:

In addition, leads with EX labels in Figures 5k-5s are connected to similarly labelled leads in Figures 5k-5s. For example, the output lead labelled EX4 in Figure 5m is connected to the input lead labelled EX4 in Figure 5l. The detailed operation of the gate array circuits shown in Figures 5k-5s will be readily apparent to those skilled in the art from the circuits themselves and from the preceding and following functional description of gate array 402 in relation to the other components of digital unit 55.

USART 400 has a REQUEST TO SEND ("RTS" or "DTRA") lead by which it interrogates communication

unit 56 to ensure that the communication unit is ready to transmit reverse data to head end 12. If communication unit 56 is ready to transmit reverse data, the communication unit sends an appropriate signal to USART 400 on the CLEAR TO SEND ("CTS" or "CTSA") lead. USART 400 selects the reverse data channel to be used by means of signals on the RE-VERSE DATA CHANNEL SELECT A and B ("RTSA" and "RTSB") leads, which are also connected to communication unit 56.

Pull-up resistor networks 404-407 are connected in the conventional way between +5V power supply circuit 414 and the CTS, RTSA, RTSB, RTS, INTERRUPT, FORWARD DATA, and REVERSE DATA leads, as well as to the TXDB and RXDB leads which are not used. Power supply circuit 414 is configured conventionally to provide noise protection for the +5V power signal used throughout digital unit 55. The VCC terminal of USART 400 is also conventionally connected to +5V power supply 414 in parallel with capacitors 408 and 409. The VCC terminal of gate array 402 is similarly connected to the +5V power supply in parallel with capacitors 410 and 411. The SYNCA terminal of USART 400 is clamped to the +5V supply via resistor 412. The PRI, CDA, and GROUND ("GND") leads of USART 400 and the GROUND ("GND") lead of gate array 402 are all connected to ground.

USART 400 applies parallel forward data to the data bus of digital unit 55 via terminals D0-D7. USART 400 also receives parallel reverse data from the data bus via terminals D0-D7. The data bus distributes data among USART 400, microprocessor 420, latches 430 and 432, multiplexers 440 and 442, microcomputer 450, and memory unit 475. Pull-up resistor network 413 is connected in the conventional way between the +5V power supply and the data bus leads.

;

Microprocessor 420, which can be a conventional microprocessor such as Intel part number 80186, performs such functions as (1) communicating with head end 12, (2) processing subscriber requests (e.g., channel selection), and (3) communicating with microcomputer 450. In addition to the data bus connections, microprocessor 420 communicates with USART 400 via its DRQ1, INTAO, DRQ0, A1, A2, PCS0, Tlour, and Toour leads. When USART 400 is to read data directly from the memory portion 55b of digital unit 55, USART 400 requests direct memory access ("DMA") for reading by applying a DRQ1 signal to microprocessor 420. Microprocessor 420 acknowledges receipt of an INTO signal from USART 400 via gate array 402 as described above by means of an INTAO output signal. When USART 400 is to write data directly to the memory portion 55b of digital unit 55, USART 400 requests direct memory access ("DMA") for writing by applying a DRQO signal to micropressor The Al output signal of microprocessor 420 is applied to USART 400 to select one of two register sets in USART 400 for connection to the data bus. The A2 output signal of microprocessor 420 is applied to USART 400 to one of two register types (i.e., control "C" or data "D") within the USART register set selected by the Al signal. The PCSO (programmable chip select 0) output signal of microprocessor 420 is used to select USART 400 for reading data from (WR) or writing data to (RD) microprocessor 420. The TOOUT output signal of microprocessor 420 is a timer signal which controls the rate at which forward and reverse data are transmitted. The TlOUT output signal of microprocessor 420 is similar to the TOOUT signal, but controls the data rate on unused channel TXDB/RXDB.

Microprocessor 420 also communicates with gate array 402 via its TOOUT, PCS2, PCS4, BHE, INTO,

RESET, CLOCK OUT ("CLKOUT"), READ ("RD"), and WRITE ("WR") leads. The TOOUT output signal of microprocessor 420 is described above. The PCS2 and PCS4 (programmable chip select 2 and 4) output signals of microprocessor 420 are similar to the PCS0 signal described above. The BHE (byte high enable) output signal of microprocessor 420 is used to allow the 16-bit data bus to be used as an 8-bit data bus. The INTO input signal of microprocessor 420 is described above in connection with USART 400 and gate array 402. The RESET, CLKOUT, RD, and WR output signals of microprocessor 420 are also described above.

Microprocessor 420 applies data and address signal information to the data bus and receives such information from the data bus via its AD0-AD15 leads. Microprocessor 420 communicates directly with microcomputer 450 via its INT1, INT3, and PCS1 leads. Microprocessor 420 applies additional control signals to memory unit 475 via its UPPER CHIP SELECT ("UCS"), MIDDLE CHIP SELECT ("MCSO"), and LOWER CHIP SELECT ("LCS") leads. The operating frequency of microprocessor 420 is established in the usual way by the circuit including crystal 421 and capacitors 422 and 423. The VCC, TOIN, Tlin, SRDY, and ARDY leads are connected to the +5V power supply in parallel with capacitors 424 and 425. The TEST, GROUND ("GND"), NMI, and HOLD leads are connected to ground. As mentioned above, the RES terminal of microprocessor 420 is connected via power detect circuit 480 (including resistors 481-486, inductor 487, transistors 488-489, Zener diode 490, diode 491, and capacitor 492) to the POW-ER DETECT input terminal of digital unit 55. The POWER DETECT terminal is connected the RESET output terminal of common power supply 60 and is used to

detect an AC power failure. When AC power is restored following a power interruption, power detect circuit 480 holds microprocessor 420 in the reset condition until sufficient time has elapsed to allow the microprocessor to re-initialize itself properly. For this purpose, the output signal of power detect circuit 480 is connected to the RESET ("RES") terminal of microprocessor 420 in parallel with capacitor 426.

Latches 430 and 432 are used to store address signal information produced by microprocessor 420 at terminals ADO-AD15 while associated data signals are transmitted or received via those same microprocessor terminals. The 1Q-8Q output leads of latches 430 and 432 collectively comprise an address bus which is connected to memory unit 475. Latches 430 and 432 are enabled by the ADDRESS LATCH ENABLE ("ALE") signal produced by microprocessor 420 and applied to the G input terminal of each latch. Power (+5V) is applied to the VCC input terminal of each latch 430 and 432 in parallel with capacitors 434-436. The OC terminals of both latches are connected to ground.

Multiplexers 440 and 442 act as an interface between 16 manually positioned switches 444, which specify the address of the ECU, and microprocessor 420 to enable the information represented by switches 444 to be read by the microprocessor in two successive 8-bit bytes. The signal for selecting ("SEL") multiplexers 440 and 442 comes from latch 432. The multiplexers are advanced or stepped by the signal applied to their OC terminals from gate array 402. Power (+5V) is supplied to the VCC terminals of multiplexers 440 and 442 in parallel with capacitors 445-447. Pull-up resistor networks 448-449 are conventionally connected between the +5V

power supply and the data input leads of the multiplexers.

Microcomputer 450, which can be a conventional microcomputer such as Intel part number 8472, performs such functions as (1) controlling communications with the subscribers via the drop cables, (2) controlling the tuner/converters in the SUS, and (3) communicating with microprocessor 420. Microcomputer 450 is connected to the data bus via its DO-D7 leads. The VDD, VCC, and SS leads of microcomputer 450 are connected to the +5V power supply in parallel with capacitors 451 and 452. lead is connected to the SEL input terminals of multiplexers 440 and 442. The P25, P24, and CS leads are connected directly to microprocessor 420 as mentioned above. The RESET, WRITE ("WR"), READ ("RD"), XTAL2, XTAL1, and T1 leads are connected to gate array 402. The RD lead is also connected to memory unit 55b. The signals on the XTALl and XTAL2 leads determine the operating frequency of microcomputer 450. Pull-up resistor network 453 is connected between these leads and the +5V power supply.

The P20-P23 and PROG terminals of microcomputer 450 are connected to conventional input/output expander 454 which may be Intel part number TMP82C43P. Expander 454 allows a small number of microcomputer input/output terminals to be connected to a larger number of input/output leads. The EA and VSS leads of microcomputer 450 are connected to ground. In a development configuration, the P17 lead of microcomputer 450 is connected via pull-up resistor 455 to the +5V power supply, and via manually operated switch 456 to ground.

Microcomputer 450 receives VLF data from communication unit 56 via its TO lead. The P16 lead is not used. Six SUBSCRIBER SELECT signals are produced by microcomputer 450 and applied to leads

P10-P15. Each of these signals is applied to a respective one of the six SUs in this ECU in order to select the one or more of the SUs which is to respond to the DATA and FUNCTION SELECT signals mentioned below. The signals on leads TO and P10-P16 pass through conventional buffering and pull-up resistor network 457, which is also connected to the +5V power supply.

The +5V power supply is connected to input/output expander 454 in parallel with capacitors 458 and 459. The CHIP SELECT ("CS") and GROUND ("GND") leads are connected to ground. The signal on lead P43 is serial DATA for use by the SU or SUs selected by the SUBSCRIBER SELECT output signals of microcomputer 450. For example, this DATA signal may be the MS coefficients used by the SUs as described above in relation to the SUs. The signals on leads P40-P42 are the three FUNCTION SELECT signals which are applied to the SUs to control their processing of the above-mentioned DATA signal. The signals on the P60-P63, P70, and P71 leads are respectively the six POWER DETECT signals produced by the SUs as described above. As mentioned above, each of these signals indicates whether or not the associated subscriber is supplying his or her share of the total AC power required for operation of the ECU. The signal on the P53 lead is the VLF data signal to be transmitted from the ECU to a selected subscriber's SPU via communication unit 56. The signals on the P50-P52 leads are also applied to communication unit 56 where they are used to control multiplexer 350 which selects the SPU that is to send or receive VLF data. The signals on leads P40-P43, P50-P53, P60-P63, and P70-P71 pass through conventional buffering and pull-up or clamping resistor network 460. Leads P72 and P73 are respectively connected to ground via manually operated

switches 461 and 462 and to the +5V power supply via pull-up resistor network 463. Switches 461 and 462 allow the ECUs in the system to be grouped in up to four different addressable banks.

Back-up power supply 464 operates during a total AC power failure to prevent loss of data in an essential portion of memory unit 55b, i.e., the portion of the memory unit selected by the LOWER CHIP SELECT ("LCS") signal. A back-up power supply includes conventional hex inverting buffer 465, resistors 466-469, capacitors 470-472, diode 473, and inductor 474. Buffer 465 may be Toshiba part number TC40H368P or an equivalent device. The back-up power is actually derived from capacitor 471 which is a relatively large storage capacitor. While the AC power is on, capacitor 471 is charged from the +5.7 volt power supply via the circuit including elements 468, 469, and 472-474. During an AC power interruption (as indicated by the reset signal applied to the 1A input terminal of buffer 465), capacitor 471 supplies +5V back-up power to energize buffer 465, to provide an LCS signal, and to provide +5V power to the portion of memory unit 475 selected by the LCS signal.

Memory unit 55b includes two conventional 16K-byte read only memories ("ROMs") 476 and 477 which store the operating program instructions for microprocessor 420. Each of ROMs 476 and 477 may be Intel part number 27128, or an equivalent device. Memory unit 55b also includes six conventional 8K-byte random access memories ("RAMs") 493-498 which store the data needed for control of the ECU. Each of RAMs 493-498 may be Toshiba part number TC5565PL-15 or an equivalent device. The connection of the various elements of memory unit 55b to the remainder of digital unit 55, as well as the

inter-connection of the memory unit elements, is entirely conventional and will be readily apparent to those skilled in the art. The UCS, MCSO, and LCS signals are used to extend the 16-bit address information to allow use of more memory than can be accessed using only 16 bits. The UPPER BANK SELECT ("BKU") and LOWER BANK SELECT ("BKL") signals produced by gate array 402 are used in combination with jumper network 478 to allow the relative amounts of ROM and RAM to be changed if desired. RAMs 495 and 496 are the memory unit elements energized by back-up power supply 464 in the event of an AC power outage as described above.

VI. Common Power Supply

To reduce the amount of power required to be supplied by the CATV system operator, the power required to operate each ECU is supplied by the subscribers served by that ECU. This is accomplished by having each master SPU apply a 60-volt AC power signal to the SPU's associated drop cable. As earlier described, the AC power signals from each subscriber are converted by each subscriber's associated SU into + and - half-wave rectified DC power signals. The + and - signals are respectively summed and applied to common power unit 60.

Figure 6 shows common power unit 60 in greater detail. As shown in Figure 6, the combined + and - power obtained from the SUs is applied to a filter/smoothing circuit 510. Filter/smoothing circuit 510 includes a plurality of filtering capacitors 514 and 516 to further remove AC ripple from the input power. A pair of series-inductances 512 remove any CATV or VLF communication signals still present with the power signal.

The output of filter/smoothing circuit 510 is a well-filtered but unregulated DC voltage.

This DC voltage output is applied to the input of a conventional switching power supply 520. Switching power supply 520 includes a step-down transformer 522 for producing as an output three AC power sig-These AC power signals are each half-wave rectified by rectifying diodes 532, 534, and 536, respectively. The outputs of diodes 532, 534, and 536 are smoothed and filtered by capacitances 543, 545, and 547 and inductances 542, 544, and 546. The outputs of the capacitance/inductance smoother/filter circuits are each applied as inputs to conventional voltage regulator circuits 530, 540, and 550, respectively. Voltage regulator circuits 530, 540, and 550 regulate the voltage appearing at their inputs to DC voltage levels of 27 volts, 12 volts, and 5 volts, respectively. These output voltages are each further filtered by output capacitors 570, 572, and 574. A fourth regulated output of 5.7 volts is obtained from the circuit comprising series-pass transistor 560, diode 562, and Zener diode 564. The output signal of inductor 546 is also used as a RESET signal for indicating an AC power failure. RESET signal is applied to the POWER DETECT input terminal of digital unit 55 as described above.

The regulated DC output voltages of common power supply 60 are used to power the circuitry of the associated ECU. Thus, +5V, +12V, and +27V signals are applied from common power supply 60 to each subscriber unit (Figure 2), as well as to analog unit 54 (Figure 3), communication unit 56 (Figure 4), and digital unit 55 (Figure 5). To ensure that each subscriber equitably shares in providing power to operate the ECU associated with that subscriber, each SU includes power detection circuitry, earlier described, to turn the SU off in the event that AC

power is not being received from the drop cable associated with the SU.

VII. Subscriber Processing Unit

Subscriber processing units (SPUs) are located within subscriber residences. Each SPU is designed to (1) accept and transmit to its associated ECU subscriber-entered data, such as channel tuning requests, pay-per-view requests, parental control requests, and other functions normally associated with the television viewer, and (2) receive data and commands from the ECU to display information to a subscriber and control on and off the operation of the subscriber's television receiver. In addition, each SPU may serve as a data input terminal to accommodate audience response, shop-at-home, and other occasional two-way activities. Figure 7 shows a typical master SPU in detail.

As shown in Figure 7, a typical master SPU is connected via plug 761 to a source of subscriber-supplied 120-volt AC power. Transformer 762 steps down this power for use by the SPU. Conventional rectifier and smoothing network 760 rectifies the AC power for application to conventional voltage regulator circuit 764. Voltage regulator circuit 764 supplies as an output ("+") all necessary regulated DC voltages required to operate the circuitry of the SPU.

In addition to supplying AC power to rectifier/filter 760, transformer 762 provides as an output a source of 60 volt, 60 Hz AC power for application to the drop cable connecting the SPU to its associated ECU. For this purpose, transformer 762 includes a separate secondary winding connected to capacitor 761 and inductor 763. Inductor 763 presents a high impedance to the relatively high frequency CATV, VLF, and reverse HDRC signals, but

presents a low impedance to the lower frequency AC power signals. AC power signals are tapped off from inductor 763 and applied to terminal 767 to which is connected the drop cable. Thus, each subscriber, via the master SPU in the subscriber's residence, provides a share of the total power required to operate the ECU to which the subscriber's SPU is connected. If the SPU of Figure 7 were a slave SPU, inductor 763 would be removed so that only the subscriber's master SPU would supply power to the drop cable.

Drop cable terminal 767 is also connected to one terminal of conventional directional coupler 778 through capacitor 765. Capacitor 765 presents a high impedance to 60 Hz AC power signals, but a low impedance to the higher frequency CATV, VLF, and reverse HDRC signals. Another terminal of directional coupler 778 is connected via combiner 779 to a terminal ("TV") to which the subscriber's television receiver 90 (Figure 1), optional FM audio receiver equipment, and optional forward HDRC utilization equipment are attached. In this way, CATV signals (including television, FM audio, and forward HDRC signals) received from the ECU are transmitted to the devices which utilize those signals. Combiner 779 adds the reverse HDRC signal for application to the drop cable. Although in the preferred embodiment, a subscriber's television, FM audio and HDRC equipment are connected to the drop cable via connection to the SPU, it will of course be appreciated that such equipment may instead be connected to the drop cable without direct connection to the SPU by utilizing a conventional directional coupler and capacitor. Thus, the present invention provides subscribers with great flexibility in variously locating the SPU and the subscribers'

television apparatus and other equipment within the subscribers' premises.

The terminal of directional coupler 778 connected to the TV and FM audio terminal is also connected to the input of conventional VLF demodulator 770. Demodulator 770 receives signals transmitted from the ECU, including CATV and VLF communication signals. As already described with respect to an embodiment of the ECU, ECU-to-SPU VLF communication signals are ASK-modulated signals having a carrier frequency of 430 KHz. This carrier signal is on continuously except when data is being transmitted. Demodulator 770 demodulates the applied ECU-to-SPU VLF signals to produce serial digital data as an output. This is accomplished in one embodiment by parallel tuned LC circuit 776 which is tuned to 430 KHz. Conventional amplifier/filter circuit 774, which in one embodiment uses a surface acoustic wave ("saw") filter as the filtering element, receives the output of circuit 776 to provide an output only when 430 KHz carrier is detected. The output from circuit 774 is then applied to operational amplifier 772 which produces an output that is high or low in response to the presence or absence, respectively, of a signal from amplifier/filter 774. Operational amplifier 772 thus produces a digital data output representative of the information transmitted to the SPU from the ECU via the VLF signal.

The digital data output of demodulator 770 is applied to a data input line and to an interrupt input line of conventional microcomputer 700. Microcomputer 700 may be any suitable commercially available microprocessor or microcomputer such as Toshiba part No. TMP 4740P, which is 4-bit microcomputer having 4k bytes of on-board ROM and 256 bytes of on-board RAM memory. An object and source code

computer program listing which will be readily understood by those skilled in the art suitable for controlling the operations of microcomputer 700 is annexed hereto at Appendix A.

Microcomputer 700 utilizes data received from the ECU to display information on conventional 7-segment display 710. In one embodiment, display 710 is capable of displaying two decimal digits representative, for example, of the television channel to which the associated SU in the ECU is tuned. Microcomputer 700 drives display 710 in a conventional manner by multiplexing display data onto a common seven-line bus B1 and alternately enabling two return lines A and B. Resistor-pack 712 includes seven resistors, each resistor being in series with a line of bus B1 to provide current limiting for display 710.

Microcomputer 700 also utilizes data received from the ECU to illuminate a so-called order event lamp. In one embodiment, the order event lamp is a conventional light emitting diode (LED) 790 connected to microcomputer 700 via current limiting resistor 792. As described in greater detail below, the order event lamp may be utlized to inform the subscriber that the subscriber is viewing a program for which the subscriber will be charged an additional fee.

Another circuit element controlled by micro-computer 700 is television power relay 791. Television power relay 791 is a normally-open relay which controls the application of 120-volt AC power to power outlet 793, into which the associated television receiver 90 is plugged. Relay 791 is controlled on and off on command from the ECU.

Also connected to microcomputer 700 is keyboard 720 for use by the subscriber, for example, in entering channel selection requests. In one em-

bodiment, keyboard 720 is a conventional membrane matrix keyboard having four columns and four rows. A common bus B2 having eight lines connects the keyboard's row and column outputs via resistor pack 722 to corresponding inputs of microcomputer 700. In addition to keyboard 720, an optional remote control unit ("RCU") may be used to enable a subscriber to remotely enter data into the SPU (see Figure 1). Such an RCU may be of any type, wired or not. In one embodiment, the RCU is a conventional wireless device which communicates with the SPU by transmitting coded infra-red light. In the SPU, conventional remote control receiver 730 having a photo-diode sensitive to infra-red light receives these coded signals and converts them into serial digital data. This data is then provided to microcomputer 700.

Microcomputer 700 communicates subscriberentered channel and other requests to the attached ECU by sending digital data to VLF modulator 740. The digital data turns transistor 742 on and off via current-limiting resistor 783. In turn, transistor 742 turns on and off FET transistor 746 via resistors 743, 745, 747, and 749. FET transistor 746 controls on and off the output of continuously operating 468 KHz oscillator 744 to ASK modulate a 468 KHz signal. Saw filter 748 provides bandpass limiting for the modulated output of modulator 740. The output of saw filter 748 is applied to an emitter-follower circuit comprising transistor 750 and resistors 752-755. Capacitor 751 blocks DC voltage. The output of the emitter-follower circuit is applied through capacitor 757 and resistor 756 to a terminal of directional coupler 778. The VLF modulated signal is then applied from directional coupler 778 to the drop cable for transmission to the attached ECU on the SPU-to-ECU communication channel.

For enabling each of a plurality of SPUs (i.e., a master SPU and one or more slave SPUs) connected to a drop cable to selectively communicate with the ECU, each SPU is given a unique address at the time the SPU is installed in the subscriber's residence. This is accomplished by placing appropriate jumper wires in jumper block 782. Jumper block 782 has 2 jumper connections, each representing one bit of a 2-bit address. By selectively jumping the terminals in jumper block 782, each SPU attached to an ECU may be assigned any of 4 different addresses. In addition, switch 780 serves to identify the SPU depending on whether the switch is opened or closed as either a master SPU associated with a primary SU in the ECU, or a slave SPU associated with a secondary SU in the ECU. Typically, the master SPUs are assigned binary address 00 in jumper block 782, and slave SPUs are assigned any address 01, 10, or 11 in jumper block 782.

Communication between the ECU and its associated SPUs is via separate transmit and receive channels over the drop cable. As mentioned above, the first channel, the ECU-to-SPU channel, is a VLF channel having a carrier frequency of 430 KHz. The second channel, the SPU-to-ECU channel, is a VLF channel having a carrier frequency of 468 KHz. Both channels carry data at a rate of 1200 bps, although other convenient data rates may be used. Each SPU associated with an ECU transmits data to the ECU on the common SPU-to-ECU channel. Similarly, the ECU transmits data to each associated SPU on the common ECU-to-SPU channel.

VIII. Head End

Elements 34 and 36 of head end 12 are shown in greater detail in Figure 8. The forward and reverse data signals on cable network 14 are

coupled to combiner 800 by combiner 32. Combiner 800 applies the forward data signal from the modulator portion 810 of modem 34 to combiner 32, and applies the reverse data signal from combiner 32 to the demodulator portion 840 of the modem.

Central control computer 36, which may be any suitable computer such as a conventional Intel 330 computer, includes conventional main central processing unit ("CPU") 880, conventional main memory 882, conventional output buffer unit 884, and four conventional main input buffer units 886-889. All of elements 880, 882, 884, and 886-889 are conventionally interconnected via communications bus 890. Depending on the data rates and the speed of operation of buffer units 884 and 886-889, it may be possible to combine the functions of units 884 and 886-889 into a smaller number of buffer units. Main CPU 880 includes or is coupled to conventional input/output devices (not shown) for use by the operators of the system to control the system.

Each of buffer units 884 and 886-889 includes a conventional high level data link ("HDLC") controller portion, a conventional CPU portion, and a conventional memory portion. The HDLC controller portion of output buffer unit 884 converts parallel forward data originated by main CPU 880 to a serial NRZI forward data signal. This forward data signal is applied to conventional EIA RS 422 interface device 812 in the modulator portion 810 of modem 34. Interface device 812 applies the forward data signal to conventional TTL buffer 814. TTL buffer 814 applies the forward data to PIN diode switch 816 which frequency modulates the forward data signal by switching back and forth between 103.9 MHz and 104.1 MHz oscillators 818 and 820 in accordance with the applied data signal. The frequency modulated forward data signal is applied to surface acoustic wave bandpass

filter 822 and then to combiner 800 for application to cable network 14 via combiner 32.

Considering now the elements which receive, demodulate, and process the reverse data signals, it will be recalled that there are four reverse data channels having frequencies of 19.125 MHz, 19.375 MHz, 19.625 MHz, and 19.875 MHz, respectively, and that the reverse data is in NRZI protocol. All of these reverse data signals are passed through conventional bandpass filter 842 and conventional preamplifier 844. The output signal of preamplifier 844 is applied to four similar demodulator circuit paths, only one of which is shown in detail in Figure 8. Each of these circuit paths demodulates the reverse data signal in a respective one of the reverse data channels.

In each of the above-mentioned circuit paths, the reverse data signal is mixed by mixer 850 with the output signal of local oscillator 852 having a frequency selected such that the associated reverse data channel signal frequency minus the local oscillator frequency equals 10.7 MHz. Mixer 850 therefore shifts the associated reverse data channel signal to 10.7 MHz. The output signal of mixer 850 is applied to bandpass filter 854 which eliminates all signals other than the 10.7 MHz modulated signal. The output signal of bandpass filter 854 is applied to conventional intermediate frequency ("IF") amplifier 856. IF amplifier 856 is augmented by conventional carrier detector device 858 which applies a request to send ("RTS") output signal to conventional EIA RS 422 interface device 866 whenever a 10.7 MHz signal is detected. Conventional Costas loop device 860 converts the 10.7 MHz data signal to a baseband data signal which is applied to interface device 866. The baseband data signal is also applied to program logic array 862 which uses the data signal and the

higher frequency output signal of oscillator 864 to produce a clock signal pulse during each bit interval in the associated NRZI data signal. This clock signal is also applied to interface device 866.

Interface device 866 applies the carrier detect, clock, and NRZI data signals to the associated input buffer device 886-889. The HDLC controller portion of the buffer device converts the serial NRZI data to parallel data suitable for further processing by central control computer 36.

IX. ECU Operation

Microprocessor 420 (hereafter sometimes the "Data Processor") is responsible for controlling the overall operation of the ECU. This responsibility includes communicating with the CCC at head end 12, initiating, implementing and coordinating various operations within the ECU, and communicating with the SPUs. The Data Processor is aided in its functions by microcomputer 450 (hereafter sometimes the "Drop Processor"). The Drop Processor is responsible for transmitting to associated SPUs messages originated by the Data Processor, and for transmitting to the Data Processor messages originated by the SPUs. In addition, the Drop Processor on command from the Data Processor controls various functions associated with the SUs of the ECU. The operations of the Data Processor and Drop Processor in communicating with the CCC at head end 12 and with associated SPUs, and in implementing and controlling various ECU functions, will now be described.

A. ECU/SPU Communication Protocol

The communication protocol between an ECU and its associated SPUs must allow for the prompt detection and servicing of channel selection, payper-view requests and other subscriber-originated

requests from any of a plurality of SPUs (both master and slave) associated with any of up to six drop cables. Moreover, the communication protocol must be capable of detecting requests which are sporadic and infrequent.

1. ECU/SPU Polling

To ensure the prompt servicing and processing of subscriber-entered SPU requests, communication access to the ECU is controlled by the ECU's digital unit 55 using a two-level polling scheme. The first level is called "drop polling", and permits a very rapid polling or sensing of each drop associated with the ECU to identify a drop which has an SPU in need of service (i.e., having information to transmit to the ECU). Drop polling is accomplished without transmitting or receiving any data over the relatively low-speed (in one embodiment, 1200 bps) ECU/SPU data link.

Once a particular drop has been identified by the ECU as requiring service, and if necessary because of the existence of more than one SPU attached to the drop, the ECU uses a second level of polling, called "device polling", to differentiate between SPUs. In this event, the communication link is used to specifically address each SPU attached to the drop to determine which SPUs require service. The ECU maintains maps in its memory of each drop, and of each device on each drop. The data of each map is in a predetermined order so as to optimize response times or to give priority to certain SPUs.

Drop Polling

Drop polling is controlled by microcomputer 450 in ECU digital unit 55 (Figure 5e) and multiplexer 350 in communication unit 56 (Figure 4). If an SPU requires service (e.g., a subscriber has

entered a channel request into the SPU's keyboard), SPU microcomputer 700 causes VLF modulator 740 to transmit a continuous 468 KHz carrier signal to the This continuous carrier signal is called a "cry" or "Service Request" signal. At the ECU, microcomputer 450 selects a drop by sending a drop address code to multiplexer 350 via the multiplexer's address lines A, B and C (Figure 4) to selectively connect the ECU's VLF modulator 320 and demodulator 340 to a particular one of the six drops. Once connected to a drop via multiplexer 350, ECU digital unit 55 listens for the presence of carrier signal (a Service Request) on the drop. If carrier signal is present on the drop and detected by the ECU, this is interpreted by the ECU to mean that an SPU on the drop requires service. If no carrier signal is detected on the drop, the ECU interprets this to mean that no SPUs on the drop require service. In this latter event, the ECU (via multiplexer 350) selects another drop in a predetermined sequence, and listens for the presence of carrier on that drop. If carrier is present, then an SPU attached to the drop requires service.

It should be noted that SPUs on the several drops request service simply by activating carrier on the SPU-to-ECU drop cable communication channel. It is not necessary for an SPU to transmit to the ECU any data or special commands to obtain service, thus allowing for very fast polling. To prevent any interference with communications already taking place on the drop, each SPU connected to the drop continuously monitors the ECU-to-SPU channel for the presence or absence of data. An SPU will activate carrier to transmit a Service Request only after the SPU has detected a predetermined number of (e.g., twelve) bit times of a continuous mark condition on the

ECU-to-SPU channel. This verifies to the SPU that there is no other communication on the drop cable.

Device Polling

Device polling is also controlled by microcomputer 450 in the ECU. As described above, if more than one SPU is attached to a drop on which a Service Request is detected, the ECU must individually poll the SPUs on the drop to determine which SPU has requested to communicate with the ECU. Irrespective of which SPU on the drop first requested service, device polling will occur in a predetermined order established by the ECU.

The ECU initiates device polling by transmitting conditional poll commands on the selected drop. All SPUs and other devices connected to the selected drop sense these commands and cease any activity (i.e., carrier transmissions) on the SPU-to-ECU link. The particular SPU being polled responds to the ECU with a single mark bit if the SPU does not require service. If the polled SPU requires service, the SPU responds by transmitting to the ECU an acknowledgement (a space bit) followed by data.

2. ECU/SPU Message Formats

The communication of messages between an ECU and its associated SPUs is asynchronous with uniform bit timings and non-uniform, indeterminate character timings. The ECU-to-SPU link completely controls data transfers on the SPU-to-ECU link.

Each character transmitted to the SPU by the ECU is acknowledged by the SPU with a one-bit acknowledged/not acknowledged ("ACK/NAK") handshake. This bit is also used for a poll response, as earlier described.

Each character is preceeded by at least one bit time of mark state. A mark-to-space transition resulting in a start bit in a space state initiates the character.

The next bit is a message framing bit, then eight data bits (transmitted low-order bit first), a parity bit, and at least one bit time of mark condition as an ending. The ending bit time of mark condition also serves as a lead-in to a possible subsequent character.

Character Framing

Character framing is established by the SPU sensing on the ECU-to-SPU link at least a predetermined number (e.g., twelve) bit times of a continuous mark condition followed by a mark-to-space transition resulting in a start bit. If an SPU loses character framing it will not recognize any commands until character framing is re-established by the ECU. The ECU periodically allows a given drop the opportunity to re-establish character framing by enforcing periods of continuous mark condition.

Message Framing

The manner in which a message character (data) is to be interpreted by an SPU is determined by the state (mark or space) of the message framing bit. The beginning of a message is indicated by a space condition (logical zero) in the message framing bit. A logical zero message framing bit means that the data field (8 bits) represents a command which all SPUs on the drop must interpret. On the other hand, if the message framing bit is in a mark condition (a logical one), then the data field is interpreted as containing subsequent information to a previous command. Any number of message characters can occur between command bytes. The incorporation of the message framing bit, although adding 1/11ths overhead to each message character, increases framing integrity and permits increased through-put when long data streams are encountered.

without the message framing bit, the transmission of long data streams to or from an SPU would be curtailed or precluded in view of the need for the ECU to be able to rapidly poll and service up to 6 drops, each drop potentially having a plurality of SPUs. By utilizing the expedient of a message framing bit, the ECU may perform drop polling or even service other SPUs on other drops during the interstices between character transmissions to a specific SPU on a particular drop.

ACK/NAK and Poll Responses

The bit time immediately following the parity bit is used as an ACK/NAK window on the SPU-to-ECU link. Each character transmitted by the ECU is acknowledged by the SPU during the ACK/NAK window. This ACK/NAK window is also used in a special manner to respond to polls.

SPUs respond to the ECU during the ACK/NAK window as follows. Upon the receipt of an initial message start bit, all SPUs on the drop turn off carrier on the SPU-to-ECU link. Upon receipt of the message framing bit, if the bit is a space, all SPUs input the data bits (which represent a command) to check for the presence of their address. If the message framing bit was a mark, then only the previously addressed SPU on the drop inputs the data bits.

Upon receipt of the last data bit, the addressed SPU turns on its carrier on the SPU-to-ECU link. Upon receipt of the parity bit, if the parity bit indicates an error in transmission, then the SPU leaves its carrier on during the next bit time as a NAK signal to the ECU. If the parity bit indicates correct transmission, then the SPU turns its carrier off and maintains the carrier off during the next bit time as an ACK signal to the ECU.

. .

If the data is a correctly transmitted poll, then the polled SPU after receipt of the parity bit turns its carrier off by transmitting the start bit of the information it has to transmit to the ECU. Otherwise, carrier is maintained on during the ACK/NAK window. One bit time after receipt of the parity bit (i.e., after the ACK/NAK window), all SPUs turn carrier off in preparation for another transmission to or from the ECU.

B. ECU/SPU Messages

Communications from the Data Processor to the Drop Processor are in the form of variable length messages representing commands which the Drop Processor executes. Execution by the Drop Processor of a Data Processor command normally follows a handshaking sequence requiring the Drop Processor to return a command response to the Data Processor. This command response may be a single byte acknowledgment, or a multiple byte response if the Data Processor command requires a return of data. However, if the Data Processor command requires the Drop Processor to send a message to a device attached to a drop cable, as described below, a command response may not be required.

In addition to command responses, information may be passed to the Data Processor from the Drop Processor without any commands having been issued by the Data Processor. Such a transfer would occur, as further described below, in the event that a device attached to a drop cable transmits a Service Request to the ECU. In such an event, the Drop Processor will read data from the device requesting service and pass the information to the Data Processor as an Unsolicited Data Response.

The following table sets forth the Data
Processor/Drop Processor communication commands uti-

lized in one embodiment of the invention. Commands having an asterisk are sent from the Drop Processor. The other commands are sent from the Data Processor.

TABLE C

COMMAND (HEX)	FUNCTION
00	Reset drop processor.
01	Read power detect and bank address.
03	Change tuner frequency (channel select).
04	Send message to attached device.
05	Turn converter on/off and select cable A or cable B.
07	Define drop poll sequence.
08	Define device poll sequence.
84*	Unsolicited Data Response from attached device.

Briefly, the commands set forth in Table C operate as follows:

Command 00. This is a one-byte command message used by the Data Processor to reset the Drop Processor and to initialize its registers and pointers. All polling activities are discontinued. The Drop Processor acknowledges receipt of this command by returning to the Data Processor a single command response byte equal to 00.

Command 01. This is a one-byte command message used by the Data Processor to cause the Drop Processor to read the state of the six power detect lines (POWER DET, Figure 2) from the subscriber units SU1, SU2, etc., and to read the bank to which the

the Drop Processor to this command comprises two bytes. The first byte echoes the command byte (01). The second byte is a data byte which specifies the state of each of the POWER DET lines and the ECU's bank address. For each of the POWER DET lines of the six subscriber units, corresponding bits 0-5 of the response byte are set to 1 or 0 depending respectively on whether or not power is being supplied to the drop cable by the subscriber connected to that subscriber unit. Bits 6 and 7 of the response data byte specify to which one of four banks the ECU's address is assigned.

message used by the Data Processor to cause the Drop Processor to tune any of the ECU's six associated SUs to a specified physical channel. The first byte is the command byte (03). Next are three bytes of data. The first byte specifies in bits 0-2 which one of the six SUs is to be tuned. The next two bytes specify the two MS numbers, earlier described, which are required by the circuitry of the SU's tuner/converter to tune to a particular physical television channel. The Drop Processor sends a two-byte command response to the Data Processor upon receipt of the command echoing the first two bytes of the command message.

Command 04. This command message (hereafter the "04 Command") is used by the Data Processor to cause the Drop Processor to send an addressed message to a device attached to a drop cable. In one embodiment, the device may be an SPU having an address equal to 2, 3, 4 or 5, or the device may be some other type of apparatus attached to the drop cable and capable of communicating with the ECU. Examples of such other devices are medical monitoring equipment, fire alarms, smoke alarms, burglary

alarms, and so forth. Such other devices may have addresses equal to 0, 1, 6 or 7.

The 04 Command message to the Drop Processor includes at least four bytes, as follows: (1) in the first byte, the command code (04), (2) in the second byte, the drop number (bits 0-2) and the device address from 0-7 (bits 3-7), (3) in the third byte, the number of bytes contained in the message, and (4) in the fourth byte, a device command. Following the device command byte are one or more data bytes. The device command and data bytes together comprise the message. The device command byte includes a 3-bit device address (bits 0-2) and a 5-bit function code (bits 3-7). The function code is used to command a particular operation in the addressed device. The following table sets forth the function codes used to control SPU or device operation in one embodiment of the invention:

TABLE D

FUNCTION CODE (HEX)	DEVICE OPERATION
00	Read internal status, and return a response message to the ECU.
01	Turn on or off the order event lamp.
02	Set the order-event lamp to flashing or non-flashing mode.
03	Enable or disable data input to the device.
04	Enable or disable data output from a device.
05	Turn the television power relay on or off.
06	Blank the display.
07	Set the display to flashing or non-flashing mode.
08	Display a character in the right-most position of the display.
09	Transmit a number of characters to the ECU as specified by the byte count of the 04 Command message.
OA	Display a character at a specified position of the display.
ОВ	Conditional poll to determine the identity of the device sending a Service Request. The device returns its data.

÷

If the device message requires the device to return a response to the ECU (e.g., in response to function codes 00, 09, or 0B), a command response (hereafter the "04 Response") is returned from the Drop Processor to the Data Processor. This response includes a three-byte response header followed by one or more data bytes. The response header includes: (1) in the first byte, a command response code (hex 04), (2) in the second byte, an echo of the drop and device address byte originally sent by the Data Processor, and (3) in the third byte, the number of bytes of data in the response message. Assuming no transmission errors occurred, following the response header are one or more response data bytes. The data byte of an error-free 04 Response to a conditional poll, for example, may identify the key which the subscriber has depressed. Or, in the case of an error-free 04 Response to a status request message, the data byte may specify by its bit settings the device status as follows: the device is a master or slave SPU (bit 7), the order event lamp is flashing (bit 5), the order event lamp is on (bit 4), the television power relay is on (bit 3), there has been recent power on (bit 2), a key has been recently depressed (bit 1), and a new character is available (bit 0). If a transmission error occurred, the byte count is 00. In this event, a single data byte follows the byte count to specify an error code. error code may be 01 (indicating an ECU-to-device transmission (parity) error), 02 (indicating a device-to-ECU transmission (parity) error), or 03 (indicating an invalid device response). Error codes are sent to the Data Processor only after the occurrence of five consecutive link transmission errors.

Command 05. This command is used by the Data Processor to cause the Drop Processor to turn on or off a particular SU and, in a two-cable system,

to cause the SU to select either cable A or cable B. The command message includes two bytes. The first byte is the command code byte (hex 05). The second byte specifies (1) the SU (bits 0-2), (2) the selected cable (bit 6 is set to 0 or 1 to select cable A or B, respectively), and (3) whether to turn the SU unit on or off (bit 7 is set to "0" or "1", respectively). A two-byte command response is returned to the Data Processor by the Drop Processor. The first byte echoes the command byte (05). The second byte includes in bits 0-2 the SU address contained in the command message.

Command 07. This command is used by the Data Processor to load a drop polling map into the Drop Processor to define the drop polling sequence. The command message includes five bytes. The first byte is a command code byte (hex 07). Bytes two through four specify the drop polling sequence. Each of these bytes is divided into two nibbles of four-bits per nibble. The value of each nibble is set from 0-5 to specify in each nibble a particular drop. Drops are sequentially polled in the order specified by the nibbles as received by the Drop Processor from the Data Processor. A value of hex F in a nibble indicates the end of the polling map. If all nibbles contain hex F, drop polling is disabled. The fifth byte would include an F in its high order nibble to indicate the end of a polling map for six drops. A one-byte command response (07) is sent by the Drop Processor to the Data Processor echoing the command code byte.

Command 08. This command is used by the Data Processor to load a device polling map into the Drop Processor to define the device polling sequence. This command message includes seven bytes. The first byte is the command byte (hex 08). The second byte specifies the drop in bits 0-2. Bytes three through

six specify in each of eight nibbles a device address. Devices on the specified drop are sequentially polled in the order specified by the device address nibbles as received by the Drop Processor from the Data Processor. A value of hex F in a nibble indicates the end of the device polling map. If all entries in the device polling map are set to hex F, device polling is disabled. The seventh byte would include an F in its high order nibble indicating the end of a device polling nap for eight devices. A two-byte command response is sent by the Drop Processor to the Data Processor echoing the first two bytes of the Data Processor's command message.

Command 84. This command (hereafter the "84 Command") is sent from the Drop Processor to the Data Processor indicating the receipt by the Drop Processor of unsolicited data from a device attached to a drop cable. The 84 Command is used by the Drop Processor to transmit to the Data Processor data received from a device which has transmitted a Service Request to the ECU (e.g., a subscriber has entered a channel selection request via SPU keyboard). This command message includes at least four bytes. The first byte contains the command code (hex 84). The second byte specifies the drop address (bits 0-2) and the device address (bits 3-7) to identify the particular drop and device sending the Unsolicited Data Response. The third byte specifies the number of data bytes being sent by the device. Finally, the fourth byte is a data byte. If the byte count is 00, an error has occurred. In such a case, an additional byte follows the data count byte specifying an error code. An error code of 01 indicates an ECU-to-SPU transmission (parity) error. An error code of 02 indicates an SPU-to-ECU transmission (parity) error.

C. Drop Processor Operation

Figures 9a-9b illustrate flow charts of a computer program utilized in one embodiment of the invention for controlling the operations of the Drop Processor. An object and source code computer program listing which will be readily understood by those skilled in the art for controlling the operations of the Drop Processor in accordance with the flow charts of Figures 9a-9b is annexed as Appendix B.

The program controlling the Drop Processor includes a Main Routine (Figure 9a) and a Timer Interrupt Routine (Figure 9b). Each of the two routines runs independently of the other. The Main Routine is periodically interrupted by the Timer Interrupt Routine, in a conventional manner, after a predetermined time period has elapsed as determined by the timing out of an interrupt timer. The function of the Drop Processor Main Routine is to (1) receive data from the Timer Interrupt Routine (e.g., a message from an SPU to the ECU) and send it to the Data Processor, and (2) to send data from the Data Processor to the Timer Interrupt Routine for, ultimately, transmission to SPUs. The function of the Timer Interrupt Routine is to (1) implement drop and device polling, (2) transmit messages to and receive messages from SPUs attached to the drops, and (3) send signals to and receive signals from the SUs.

1. Main Routine

As shown in Figure 9a, the program flow of the Main Routine begins at step 901 where various buffers, counters, flags and ports are initialized. Also at step 901, drop polling and device polling are initialized, and register R5 (described in more detail below) is set to three. At steps 902 and

903, the address for jumping to the Timer Interrupt Routine is set and the interrupt timer is activated.

Initialization is complete when the program flow advances to step 904. At step 904, the Main Routine interrogates the state of an Input Buffer Full ("IBF") flag. This flag is associated with a Drop Processor buffer which receives data passed to the Drop Processor from the Data Processor. If the IBF flag indicates that the input buffer is full, the program flow advances to step 905. Otherwise, the program flow branches to step 906.

Assuming first that the IBF buffer is not full the program advances to step 906, where the Drop Processor checks a buffer (the 84 Buffer) to determine whether or not a device attached to a drop has sent an Unsolicited Data Response (i.e., an 84 Command). If so, the program advances to step 907 to pass the 84 Command to the Data Processor. Otherwise, the program advances to step 908 where the Drop Processor determines if a device has sent an 04 Response. If "no", the program loops to step 904 to again check the IBF flag as earlier described. If "yes", the program advances to step 909 to pass the 04 Response to the Data Processor. From step 909 (or step 907 if the program advanced to that step), the program loops to step 904.

If at step 904 the IBF flag indicates that the input buffer is now full, the program advances to step 905 where the contents of the buffer are input and the IBF flag is cleared. The program flow then advances to step 910 where the Drop Processor determines what type of command (earlier described) was included in the message sent by the Data Processor. Depending upon the command, the program at step 910 may branch in any of three directions.

If command 00 (reset) was sent, the program flow advances to step 920, where the Drop Processor

sends a 00 command response message to the Data Processor via an output buffer associated with the Drop Processor. The program flow then loops to step 901 to re-initialize the Drop Processor as previously described.

If at step 910 any of commands 00, 03, 05, 07 or 08 was sent by the Data Processor, the program flow advances to step 911. At step 911, the Drop Processor processes the particular command as earlier described. The program flow then advances to step 912, where the Drop Processor sends to the Data Processor an appropriate command response. From step 912, the program flow loops to step 904.

Finally, if step 910 determines that an 04 Command message was sent by the Data Processor, the program flow branches to step 913. At step 913, the Main Routine interrogates a flag indicating the state (empty or full) of an "04 Buffer" associated with the Drop Processor. The 04 Buffer contains data to be sent by the Drop Processor to a device attached to a drop. If the 04 Buffer is empty, the program branches to step 914. Otherwise, the program branches to step 915.

step 914 (i.e., the 04 Buffer is empty), step 914 places data received from the Data Processor into the 04 Buffer. The program flow then advances to step 917, where register R5 is checked. If the contents of register R5 are not equal to 0, the program branches to step 919 to decrement the contents of register R5 by one. Otherwise, the program advances to (1) step 918, where the contents of register R5 are initialized to a value of three and incremented by one, and (2) step 919 where the contents of register R5 are decremented by one. From step 919, the program flow loops to step 904 to again check the input buffer.

Returning now to step 913, if the 04 Buffer is not empty the program branches to step 915. At step 915, the Main Routine determines whether or not the 04 Buffer contains an 04 Response from an attached device. If "yes", the program advances to step 916 to pass that 04 Response data to the Data Processor. From step 916, the flow advances to step 914 to input the data received from the Data Processor. On the other hand, if "no" at step 915, the program advances to step 921 where the contents of register R5 are checked. If the contents of register R5 are not equal to 0, the program loops to step 913 to again interrogate the state (empty or full) of the 04 Buffer. Otherwise, the program from step 921 advances to step 922 to check the state of the 84 Buffer. If the 84 Buffer is empty, the program immediately loops to step 913. However, if the 84 Buffer contains data at step 922, the program advances to (1) step 923 to pass the data to the Data Processor as an 84 Command, (2) step 924 to reset the R5 register to a count of three. The program then loops to step 913.

2. Timer Interrupt Routine

A flow chart of the Timer Interrupt Routine is illustrated in Figure 9b. As shown in Figure 9b, the Timer Interrupt Routine starts at step 950 to initialize the drop and device maps and clear various flags and buffers. The program then advances to step 951, where a determination is made as to whether ("yes") or not ("no") a Service Request exists on the drop to which the Drop Processor is connected via multiplexer 350 (Figure 4).

Assuming first that no Service Request is detected at step 951, the program branches to step 966 where the 04 Buffer is checked to determine whether or not the Drop Processor has received an 04

Command from the Data Processor for transmission to a device attached to a drop cable. If not, the program advances to step 960 to update the drop polling map pointer. If the pointer is not pointing to the end of the drop map, the program increments the drop map pointer in step 965, initializes the device map pointer to the beginning of the device map, and loops to step 951 to listen for the presence of a Service Request on another drop. On the other hand, if at step 960 the program determines that the drop pointer is at the end of the drop map, the program advances to step 961 to reset the drop map pointer to the beginning of the drop map prior to advancing to step 962 and then to step 951 as described above.

Returning to step 966, if the 04 Buffer contains an 04 Command to send to a device, the program flow advances to step 973 after setting a flag ("1") in step 967. At step 973, the Drop Processor transmits the 04 Command message to the appropriate device. The program then advances to step 974 to determine whether or not a transmission error occurred. If an error occurred, the program branches to step 972. If less than five errors have occurred, the program advances from step 972 to step 973 to re-transmit the 04 Command. On the fifth error, however, the program branches from step 972 to step 975 where an 04 Response containing an appropriate error code is transmitted from the Drop Processor to the Data Processor as earlier described. From step 975 in the event of an error, or step 974 in the event of no error, the program advances to step 976 to check the state of the "1" flag. Because the program advanced from step 967, the "1" flag will earlier have been set. Accordingly, the program from step 976 advances to step 960 to increment or initialize the drop map pointer as previously described.

Assuming now that a Service Request is detected at step 951, the program advances to step 952 where a conditional poll command (earlier described) is transmitted on the drop on which the Service Request was detected. At step 953, the Drop Processor determines whether an ACK or a NACK (earlier described) is returned in response to the poll. Assuming first that a NACK is returned, the program branches to step 968 to determine whether or not a transmission error occurred. If "yes", the program advances to step 969 to return an appropriate error code to the Data Processor. Otherwise, the program advances to step 970 to determine whether or not an 04 Command has been received from the Data Processor for transmission to a device. If "yes", the program advances to step 973 to transmit the 04 Command as previously described. Otherwise, the program advances to step 959 to determine whether or not the device map pointer is at the end of the device poll map. If the program is not at the end of the device map, the device map pointer is incremented at step 963 and a conditional poll command to the next device is sent at step 952. If the program is at the end of the device map, the program advances from step 959 to step 960 to update the drop map pointer and loop as previously described.

Assuming now that an ACK is detected at step 953 (signifying that the polled device has an Unsolicited Data Response to transmit to the ECU), the program advances to step 954 to input the unsolicited data. Steps 955, 956 and 964 determine as previously described with respect to steps 972, 974 and 975 whether or not five transmission errors occurred. In the event of five errors, an appropriate error code is sent to the Data Processor at step 964. From step 964 or step 955, the program advances to step 957 to check an output buffer full ("OBF")

flag indicating whether the Drop Processor's output buffer to the Data Processor is full or empty. the buffer is empty, the program advances to step 958 where the unsolicited data is sent to the Data Processor as an 84 Command via the Drop Processor's output buffer. The program then advances to step 959 to update the drop and device map pointers as previously described. Alternatively, if the output buffer is full at step 957, the program advances to step 971 to determine whether or not the Data Processor has sent an 04 Command to the Drop Processor for a device attached to a drop cable. If there is no 04 Command to send at step 971, the program loops to step 957. On the other hand, if there is an 04 Command to transmit, the program advances to step 973 to transmit the 04 Command as previously described. At step 976, because the "1" flag this time is not set, the program loops back to step 957.

D. CCC/ECU Communication Protocol

1. Message Format

A typical data message format used in one embodiment of the invention for communicating information between the central control computer (CCC) at head end 12 and the plurality of ECUs connected to cable network 14 will now be described with reference to Figures 10 and 11.

A basic message format for data communication in the forward direction (i.e., from the CCC to an ECU) is illustrated in Figure 10a. As shown in Figure 10a, each message is of a predetermined format, comprising: a FLAG byte, two ADDRESS bytes specifying an ECU address, a BYTE COUNT byte ("N"), a COMMAND byte ("CMD"), a plurality of DATA bytes, two CYCLIC REDUNDANCY CHECK ("CRC") bytes, and another FLAG byte. Each byte is comprised of 8 bits.

The FLAG bytes identify the beginning and end of a message. Each FLAG byte has a unique bit pattern ("01111110"). At the end of a message, if there are no more messages available for transmission by the CCC, the CCC transmits repetitive FLAG bytes to maintain synchronization on the communications link. Otherwise, the end FLAG byte serves as the start FLAG byte of the next message.

The two ADDRESS bytes typically specify the address of a particular ECU from 0001 (hex) through FFFE (hex). The use of two ADDRESS bytes in this matter to specify an ECU address allows the CCC to uniquely address a message to any particular one of 65,534 ECUs. The first address byte (ADH) specifies the high-order part of the address, and the second byte (ADL) specifies the low-order part. Two addresses have special meanings. Address FFFF (hex) is a global or broadcast address. All ECUs respond to a message containing the broadcast address. Address 0000 is a "mask" address, described in detail below.

The BYTE COUNT byte (N) specifies the number of bytes following in the message, exclusive of CRC and FLAG bytes. Following the BYTE COUNT byte is a COMMAND byte (CMD). As discussed in detail below, the COMMAND byte specifies the type of message being transmitted and the manner in which subsequent DATA bytes should be interpreted.

The CRC bytes (CRH and CRL) are two bytes which together form a conventional 16-bit CRC number. These two bytes are derived from a mathematical manipulation of all bits (exclusive of the FLAG bits) preceding the CRC bytes, and serve as a check that the message was accurately transmitted to and received by the ECU. The derivation of the CRC bytes is accomplished in a conventional manner in

accordance with standards promulgated by international standards organizations, such as the CCITT.

The use of ADDRESS 0000 (the mask address) enables a message to be directed to any particular ECU or group of ECUs. The basic format of a message having an address of 0000 is illustrated in Figure 10b. As shown in Figure 10b, a message having a mask address equal to 0000 differs from a basic message (Figure 10a) by the inclusion of four additional bytes following the ADDRESS bytes. These four bytes are two MASK bytes ("MH" and "ML") followed by two REFERENCE bytes ("RH" and "RL"). Any ECU receiving a message having a 0000 mask address will logically AND the ECU's unique address with the values of the MASK bytes. If the result of this logical operation equals the values set forth in the REFERENCE bytes, the ECU will recognize the message as addressed to it and respond accordingly. Otherwise, the ECU will ignore the message. As will be readily apparent to those skilled in the art, the use of the mask address in this manner allows a single message to be transmitted to any one or a selected group of ECUs. For example, if the MASK bytes are 0001, and if the REFERENCE bytes also are 0001, then all ECUs having odd addresses will respond to the message. On the other hand, if the REFERENCE bytes are changed to 0000, then all ECUs having even addresses will respond to the message.

A basic message format in the reverse direction (i.e., from the ECUs to the CCC) is shown in Figure 11, and is similar to the format for forward communication shown in Figure 10a. Thus, unique FLAG ("01111110") bytes are used to identify the beginning and end of a message. Following the beginning FLAG byte are two ADDRESS bytes which specify the address of the particular ECU sending the message. Next follow a BYTE COUNT byte (N), a

COMMAND byte (CMD), and DATA bytes. Two conventionally derived CRC bytes follow the last DATA byte as earlier described.

Referring now to Figures 12 through 17, there are shown illustrative examples of several typical messages sent between the CCC and an ECU in one embodiment of the invention. The messages of Figures 12 through 17 are formatted in accordance with the basic message formats of Figures 10-11.

Figure 12 illustrates a WRITE message sent from the CCC to an ECU. The WRITE message may be used to write a program or data to any one or a plurality of ECUs commencing at a specified address in the ECU's memory. The use of the WRITE message in this way enables the cable system operator to add new functions and services to the ECU, or to modify existing ones. Thus, the operation of the cable system may be readily enhanced or modified without having to replace or modify the ECU or SPU hardware.

The WRITE message may be used to implement a variety of functions in an ECU. For example, the WRITE message may be used to download a Channel Authorization Map in an ECU specifying which television channels each associated subscriber is authorized to view. In one embodiment, the Channel Authorization Map comprises a string of 128 bytes of data stored in the ECU's memory, each byte associated with a different one of 128 so-called logical channels. A logical channel is that channel which a subscriber requests by entering a channel number into the SPU. Each of the first six bits of each byte in the Channel Authorization Map is associated with a different one of six SUs. A bit is set to "1" or to "0" depending respectively on whether or not the subscriber associated with that bit and SU is authorized to view the television channel associated with that byte. To transmit a Channel Authorization Map to an ECU, a

WRITE command may be used specifying the start address of the map in the ECU's memory and the 128 bytes of logical channel data. The use of the WRITE command to transmit a new or replacement Channel Authorization Map enables the cable operator to add or delete authorized channels for particular subscribers as a function, e.g., of whether or not the subscriber has paid his or her bill, whether the subscriber has requested to subscribe to view additional or fewer channels, and so forth.

As another example, the WRITE command may be used to transmit to an ECU a so-called Channelization Map specifying a correlation between logical channels and physical channels. As earlier described, physical channels are the channels carried on the CATV feeder cable to which the converter/tuner in the SU tunes in response to subscriber requests to view a particular logical channel. For example, the Channelization Map might correlate logical channel 7 with physical channel 52, logical channel 9 with physical channel 15, and so on. In one embodiment having a single feeder cable, the Channelization Map in each ECU includes 128 bytes of data (in a two cable system, the Channelization Map would include 256 bytes of data). The data are grouped in pairs such that each pair of bytes is associated with a different one of 64 (or 128 in a two cable system) logical channels. Thus, the first byte pair is associated with logical channel 0, the second byte pair with logical channel 1, and so on. Each pair of bytes specifies the two MS numbers, earlier described, which are the tuning information required by the converter/tuner of each SU to tune to a particular physical channel. By changing the values of the MS numbers in the Channelization Map using the WRITE message, the CCC can dynamically (i.e., on any given day and at any given time) re-define the logical

channel/physical channel correlation. This allows the cable system operator to transmit a television program on any available physical cable channel while allowing the subscriber to always view that program by selecting the same logical channel. This is important in situations of large amounts of noise on a particular physical channel which degrades the television signal. In such an event, the system operator can transmit a new Channelization Map to redefine the physical channel/logical channel correlation to associate a less noisy physical channel with the logical channel, and transmit the program on the less noisy channel. The subscriber, however, will still access the channel carrying the program the subscriber desires to view by keying into the SPU the same logical channel number.

As shown in Figure 12, a WRITE message includes the usual two ADDRESS bytes (ADH and ADL) specifying the particular ECU to which the message is directed, and a BYTE COUNT byte (N) specifying the number of bytes following in the message. Next appears a COMMAND byte equal to hex FC ("11111100"). This COMMAND byte identifies the message as a WRITE message. After the COMMAND byte is a DATA COUNT byte (NN) specifying the number of bytes of data contained in the WRITE message to be written to the ECU's memory. Next, two bytes ("MDL" and "MDH") specify in low and high order parts, respectively, the specific ECU memory address at which the write operation should commence. Finally, there follow NN bytes of data to be written to the ECU's memory.

Another message sent from the CCC to an ECU is a READ message, illustrated in Figure 13a. A READ message enables the CCC to obtain one or more bytes of data from an ECU commencing at a specified address of the ECU's memory. The READ message may be used for a variety of purposes. For example, the

READ message may be used to determine which subscribers are authorized to view which channels, which subscribers should be charged a fee for viewing payper-view programs, and so forth. Also, the READ message may be used to examine various portions of an ECU's data or program memory to diagnose faulty or failing ECUs.

As shown in Figure 13a, a READ message includes the usual ADDRESS (ADL and ADH) and BYTE COUNT (N) bytes. After these bytes is a COMMAND byte which may be any value equal to hex F8, F9, FA or FB (11111000, 11111001, 11111010 or 11111011). Each COMMAND byte F8 through FB specifies that the message is a READ message. However, each COMMAND byte also specifies by the values of the two least significant bits on which one of the four available reverse channels the ECU should return data to the Thus, COMMAND bytes F8, F9, FA and FB specify that the ECU should return data to the CCC on reverse channel 00, 01, 02 and 03, respectively. Following the COMMAND byte is (1) a DATA COUNT byte (NN) specifying how many data bytes to return to the CCC, and (2) two memory address bytes (MADL and MADH) specifying in low and high order parts the ECU memory address at which the data READ operation should commence.

In response to a READ message, the ECU returns to the CCC on the specified reverse channel a message as shown in Figure 13b which includes the data requested by the READ message. The returned message includes the usual ADDRESS and BYTE COUNT bytes, followed by a COMMAND byte set to the value of the read command to which the return message is responsive. Next follow a DATA COUNT byte (NN) specifying the number of bytes of returned data, and the NN bytes of data requested by the READ message.

Still another message sent from the CCC to an ECU is an ECHO BACK message, illustrated in Figure 14. An ECHO BACK message causes an addressed ECU to return to the CCC on a specified reverse channel a message which is identical to that received by the ECU. The ECHO BACK message may be used to test the cable network for signal degradation and transmission errors, and may also be used to locate non-operating ECUs.

As shown in Figure 14, an ECHO BACK message includes the usual ADDRESS (ADL and ADH) and BYTE COUNT (N) bytes. Next is a COMMAND byte which may be any value equal to hex F0, F1, F2 or F3 (11110000, 11110001, 111100010 or 11110011). As previously described with respect to the READ message, the last two bits of the COMMAND byte specify on which one of the four reverse channels the ECU should echo back the CCC's message. After the COMMAND byte is a DATA COUNT byte (NN) followed by NN bytes of data.

In response to the receipt of an ECHO BACK message, the addressed ECU returns a message to the CCC as shown in Figure 14b on the specified reverse channel. Irrespective of the manner in which the message was addressed to the ECU (i.e., using a global, mask or specific address), the ECU's message includes the responding ECU's unique address in the ADH and ADL bytes, followed by a BYTE COUNT byte (N). Thereafter, the returned message is (assuming no transmission errors) identical to that originally sent from the CCC.

Yet another message sent from the CCC to an ECU is a FORCE TUNE message, illustrated in Figure 15. This message is used to cause an addressed ECU to force tune any drop associated with that ECU to any channel. Force tuning may be used, for example, to cause all subscriber television sets connected to

the CATV system to tune to a channel on which instructions and news may be communicated to subscribers in the event of a civil emergency. Also, this message may be used to automatically tune a subscriber's television set at the appropriate date and time to a channel carrying a pay-per-view program (such as a boxing match) which the subscriber requested to view.

As shown in Figure 15, a typical FORCE TUNE message includes the usual ADDRESS (ADL and ADH) and BYTE COUNT (N) bytes. Next follow a COM-MAND (CMD) byte equal to hex F4 (11110100) to identify the message as a FORCE TUNE message, and a DATA COUNT byte (NN) equal to 2. Thereafter, a SUBSCRIBER UNIT (SU) byte specifies the particular subscriber unit to be force tuned. In one embodiment, the SU byte specifies any one converter using the byte's three least significant bits. This requires a FORCE TUNE message to be transmitted for each converter to be force tuned. Alternatively, each bit of the SU byte may be associated with a different one of six converters such that a single message to an ECU can force tune more than one converter associated with the ECU. Finally, a logical channel (LC) byte specifies the logical channel number to which the specified converter should be force tuned. If the SU byte is associated with more than one converter, there would be a plurality of LC bytes, one for each converter being force tuned.

Another series of messages sent from the CCC to an ECU are SEND FUNCTION messages. These messages are used to cause an ECU to return to the CCC so-called send function data accumulated by the ECU from the ECU's associated subscribers. Send function data is data keyed into SPUs by subscribers in response to requests for such data from the CCC at head end 12. For example, send function data may represent voting or shop-at-home data keyed in by

subscribers in connection with interactive viewer preference or shop-at-home services offered by the cable operator. In one embodiment, each ECU maintains in its memory a plurality of so-called send function bytes arranged in pairs. Each pair of send function bytes is associated with a different one of up to six subscribers. The first byte specifies the subscriber with which the byte pair is associated. The second byte contains the send function data. addition to the byte pairs, the ECU maintains in its memory a send function count byte specifying the number of send function bytes in the ECU's memory. If the ECU's memory contains no send function data (e.g., no associated subscriber has entered send function data), the value of the send function count byte is zero.

In one embodiment of the invention there are six SEND FUNCTION messages. These messages are illustrated in Figures 16a through 16c. The first message is the SEND FUNCTION ENABLE message, shown in Figure 16a. In addition to the usual ADDRESS and BYTE COUNT bytes, this message has a command byte equal to hex 80, a DATA COUNT byte (NN), and a single DATA byte (SU). Each bit 0-5 of the (SU) byte is associated with a different one of six SUs. The SEND FUNCTION ENABLE message is used by the CCC to enable or disable the send function in an ECU with respect to particular SUs associated with that ECU. The send function with respect to a particular SU is enabled or disabled depending respectively on whether the setting of the bit of the SU byte associated with that SU is set to "1" or to "0".

The second message is the SEND FUNCTION CLEAR message, shown in Figure 16b. This message includes a COMMAND byte equal to hex 81, and a DATA

.... -----

COUNT byte (NN) equal to 0. In response to the receipt of this message, the addressed ECU clears the send function data in its memory.

The third message is the SEND FUNCTION DATA message, shown in Figure 16c. This message includes a COMMAND byte which may have any value equal to hex 84, 85, 86 or 87 (10000100, 10000101, 10000110 or 10000111). Upon receipt of this message, an addressed ECU will return to the CCC the send function data in its memory only if the ECU has any send function data to send to the CCC (as determined by the value of the ECU's send function count byte). As previously described with respect to the READ message, the data will be returned by the ECU on the reverse channel (00, 01, 02 or 03) specified by the values of the two least significant bits of the SEND FUNC-TION DATA message's COMMAND byte. In response to a SEND FUNCTION DATA message, the ECU sends a message to the CCC which includes one or more pairs of data bytes, each pair associated with a different SU. The first byte of the pair specifies an SU (from 0-5), and the second byte is the send data for that SU.

Yet another message available to be sent from the CCC to an ECU is a PAY-PER-VIEW message. This message is used to (a) force tune an SU to a pay-per-view event requested by the subscriber, and (b) turn on the subscriber's television apparatus via the subscriber's SPU power relay.

The PAY-PER-VIEW message used in one embodiment of the invention is shown in Figure 17 as including a COMMAND byte equal to hex 88. Next follows a DATA COUNT byte (NN). A PROGRAM NUMBER (PN) byte specifies the so-called program number, described in more detail below, to which the message relates. Finally, two MS bytes specify the MS numbers, earlier described, required to tune the con-

verter/tuner circuitry contained in the SUs to the particular physical channel carrying the pay-per-view event specified by the PROGRAM NUMBER byte.

The PAY-PER-VIEW message in one embodiment of the invention operates as follows. Each ECU includes an Event View byte in its memory. Each of bits 0-5 of this byte is associated with a different one of up to six SUs. When a subscriber tunes to a pay-per-view event, a bit of the Event View byte associated with the SU tuned to the pay-per-view event is set to "1". That bit is reset to "0" when the SU is tuned to a channel not associated with a pay-per-view event, or when the subscriber via the SPU turns off his or her television receiver. The Event View byte is used, as later described, to control the incrementing of a timer.

In addition to the foregoing, each ECU has a Program Event Map in its memory comprised of 128 pairs of bytes. Each byte pair of this map is associated with a different one of 128 program numbers. Each program number is associated with a different pay-per-view program event. Thus, the first byte pair of the Program Event Map is associated with program number or event 0, the second pair with program number or event 1, and so on. The byte pairs contain the MS numbers conveyed by the PAY-PER-VIEW message.

In addition to the Program Event Map, each ECU includes in its memory a Program Authorization Map. This map includes 768 bytes arranged in six groups of 128 bytes per group. Each group of 128 bytes is associated with a different SU, and each byte of each group is associated with a different one of 128 pay-per-view events. If a subscriber associated with a particular SU is authorized to view pay-per-view programs, and requests via

the subscriber's SPU to view a particular pay-perview program, the three least significant bits of the byte associated with that program and SU are set to the address of the SPU from which the pay-perview request was received. The five most significant bits of the byte, each initially zero, are used as a preview timer as later described.

To order a desired pay-per-view event, a subscriber enters the program number associated with the pay-per-view event into the keyboard of the subscriber's SPU. If the subscriber is authorized to view pay-per-view events, the address of the SPU from which the request was received is placed in the appropriate byte of the Program Authorization Map as described above. When the event begins, the CCC transmits a PAY-PER-VIEW message specifying the program number and the MS tuning data required by the converter/tuners of the SUs to tune to the program. If a subscriber has requested to view the pay-perview program specified in the PAY-PER-VIEW message, the ECU force tunes the SU associated with that subscriber to the channel carrying the pay-per-view event. In addition, the ECU sends a command to the SPU to cause the SPU to (1) flash the SPU's eventorder LED to signify that the subscriber is viewing a pay-for-view event during the preview period, and (2) turn on the SPU's television relay to supply power to the subscriber's television set. Thus, at the appropriate date and time, the ECU will turn on and force tune the subscriber's television set to the requested pay-per-view event. Also, the ECU will initiate operation of a preview period timer. During the preview period, a subscriber may view the pay-per-view event free of charge. If the subscriber views more than a predetermined number of minutes of the pay-per-view program, the preview timer will time out and the ECU will send a command to the SPU

to cause the event-order LED to glow continuously to signify that the subscriber will be charged a fee for viewing the event.

The preview timer operates as follows. Upon the timing out of a pay-per-view event timer, the ECU checks the state of the bit flags in the Event View byte. If the bit associated with an SU is set to "1", then a bit of the preview timer associated with the SU and program to which the SU is tuned (described above) is set to "1". Each of the five bits of the preview timers in the Program Authorization Map represents a fraction (i.e., onefifth) of the preview period. Each time that the pay-per-view event timer times out, and if the associated bit of the Event View byte is set to "1", another one of the five bits of the appropriate preview timer is set by the ECU. When all five bits of the preview timer have been set, the preview period is over and the subscriber will be charged for the pay-per-view event. The CCC periodically collects the preview timer information contained in the Program Authorization Map using READ messages to determine which subscribers should be charged for viewing which pay-per-view events.

Although several messages have been described in detail with respect to an embodiment of the invention, it will be apparent to those skilled in the art that the message format utilized in the present invention can accommodate numerous other messages sent between the CCC and the ECUs. It will also be apparent to those skilled in the art that the basic format of the CCC/ECU messages may be changed.

E. Data Processor Operation

The operation of the Data Processor will now be described for an embodiment of the invention using the message formats and messages illustrated in Figures 10-17. A source and object code computer program listing which will be readily understood by those skilled in the art for controlling the operation of the Data Processor is annexed at Appendix C.

Figure 18a illustrates the overall programmed operation of the Data Processor. As shown in Figure 18a, data received from the CCC is placed by USART 400 of digital unit 55 (Figure 5) in FIFO receive buffer 1001. This buffer is organized as a 256 x 4 byte buffer such that it can hold up to four 256-byte CCC messages at any one time. A buffer counter associated with the Data Processor points to the next empty buffer in the FIFO. Two other buffers shown in Figure 18a are FIFO output buffer 1002 and FIFO input buffer 1003. Data received by the Data Processor from the Drop Processor is placed in output buffer 1002. Similarly, data passed to the Drop Processor from the Data Processor is placed in FIFO input buffer 1003. Each of these buffers contains 256 bytes and may buffer up to 25 10-byte messages. A buffer counter associated with each buffer points to the next empty buffer. The Data Processor receives data from FIFO buffers 1001 and 1002, operates on the data (Figure 18a, item 1004), and sends data to FIFO buffer 1003 or to the CCC.

Figure 18b illustrates a flow chart of a routine by which the Data Processor determines whether or not a message has been received from the CCC and, if so, whether or not the message is for that ECU. The routine of Figure 18b is called whenever the Data Processor is interrupted by USART 400 (Figure 5) to signify that a message has been received from the CCC.

The routine of Figure 18b commences at step 1021, where the routine inhibits further input from USART 400 and determines from the CRC bytes of the received message whether or not a transmission error occurred. If an error occurred, the routine branches to step 1028 where input from USART 400 is again enabled. After step 1028, the interrupt service routine advances to step 1029 and returns to the calling program.

Alternatively at step 1021, if no transmission error occurred, the routine advances to step 1022 where the Data Processor checks the address bytes of the received message. If the address bytes match the ECU's address, the routine advances to step 1027 where the buffer counter associated with FIFO buffer 1001 (Figure 18a) is incremented by one. The routine then advances to step 1028 where USART 400 is enabled as earlier described. Because the buffer counter value was incremented at step 1027, a subsequent CCC message received by USART 400 will be written into the next buffer and will not overwrite the contents of the buffer containing the previously received CCC message.

Returning to step 1022, if the address bytes of the received message do not match the ECU's address, the routine branches to step 1024, where the address bytes are checked for the presence of the global or broadcast address (hex FFFF). If this address is present, the message is for the ECU and the routine advances to step 1027 as previously described. Otherwise, the routine advances to step 1025 where the Data Processor checks for the mask address (hex 0000) in the CCC's message. If this address is not present, the message is not for the ECU and the routine branches to step 1028. Otherwise, the routine advances to step 1026 where the mask operation is performed as earlier described.

The routine then branches to step 1027 or to step 1028 depending respectively on whether or not the result of the mask operation performed at step 1026 indicates that the message is for the ECU.

The operating program of the Data Processor will now be described with reference to Figures 18c through 18h. This program is comprised of two major parts: (1) a main routine, and (2) a collection of application programs to implement various functions within the ECU. The main routine is a task-driven program which branches to one or another application program depending upon the task to be performed. The application program performs its task (e.g., inputting keypress data from an SPU such as subscriber-entered channel requests, pay-per-view requests, send function data, etc.) and returns to the main routine. Because of the need to service a plurality of SPUs on a plurality of drop cables, it may occur that an application program must return to the main routine before the application program has completed its particular task. For example, if a subscriber enters a two-digit channel request into an SPU keyboard, the application program associated with that function may input the first digit and return to the main routine prior to the subscriber entering the second digit. In this event, the application program prior to returning to the main routine sets a time out value in a time table and a jump address in a jump address table. As more fully described below, the time out and jump address values enable the main routine to jump back to the application program at the appropriate time to continue at the point the application program left off.

Figure 18c illustrates a flow chart generally illustrating the operation of the main routine. As shown in Figure 18c, the main routine begins at

step 1005 upon ECU power up. At step 1005, the Data Processor initializes I/O and memory maps, an interrupt timer, direct memory access, and various registers and counters. The program then advances to step 1006, where the Data Processor initializes USART 400. At step 1007, the Data Processor 420 checks whether or not its back up memory requires initializing. If so, the program advances to step 1008 to initialize the back up memory. Otherwise, or after completing the back up memory initilization in step 1008, the program advances to step 1009 where other memory locations are initialized. Generally, steps 1008 and 1009 initialize such items as the Channel Authorization Map, Channelization Map, parental control codes, Program Event Map, Program Authorization Map, and so forth. In steps 1010, 1011 and 1012, the Data Processor initializes the drop and device polling maps and pointers.

After initialization, the Drop Processor enters a main loop. The main loop is illustrated in the flow chart of Figure 18d. As shown in Figure 18d, the Data Processor in the main loop sequentially determines whether or not any of four events have occurred, viz., whether or not (1) the Data Processor has received a message from the CCC (step 1013), (2) a 100/64 millisecond pay-per-view eevent timer has timed out (step 1014), (3) the Drop Processor output buffer contains data for the Data Processor (step 1015), and (4) a pay-for-view event timer has timed out (step 1016). If any of the foregoing events have occurred, the Data Processor at the appropriate step 1013, 1014, 1015 or 1016 branches to an associated operation routine shown in Figure 18d as Operate 1, Operate 2, Operate 3 and Operate 4, respectively. Otherwise, the program advances to the next numbered step in Figure 18d. After step

1016, or after an operation routine, the program flow loops to step 1013.

The operation routines of Figure 18d will now be described with reference to Figures 18e-18h.

Operate 1 Routine

If the main routine detects at step 1013 (Figure 18d) that a message addressed to the ECU has been received from the CCC, the program branches to the Operate 1 routine, shown in Figure 18e, to respond to the CCC message.

The Operate 1 routine commences at step 1030, where the Data Processor loads a CCC message from buffer 1001 (Figure 18a) into working memory. The program then advances to step 1031, where the COMMAND byte of the CCC message is checked to determine what action the Data Processor should take.

At step 1031, if the COMMAND byte of the CCC message is hex F0-F3 (ECHO BACK), the program advances to step 1032 to transmit (echo) the received message back to the CCC. After transmitting the message, the program advances to step 1041 and returns to the main loop as earlier described.

If the COMMAND byte at step 1031 is hex FC (WRITE), the program advances to step 1033 to store the data contained in the WRITE message commencing at the location of the ECU's memory. From step 1033, the program advances to step 1034 and returns to the main loop as earlier described.

If the COMMAND byte at step 1031 is hex F8-FB (READ), the program advances to step 1035 to transmit to the CCC data from the ECU's memory specified in the WRITE message. From step 1035, the program advances to step 1043 and returns to the main loop as earlier described.

If the COMMAND byte at step 1031 is hex F4 (FORCE TUNE), the program advances to step 1037 where

the converter of the specified SU is tuned to the specified channel, the SPU seven-segment display is set to display the logical channel to which the SU is being force tuned, and the power relay of the SPU associated with the SU is activated to turn on the subscriber's television. The program then advances to step 1038 and returns to the main loop as earlier described.

If the COMMAND byte at step 1031 is hex 80 (SEND FUNCTION ENABLE) or hex 81 (SEND FUNCTION CLEAR), the program advances respectively to step 1039 to enable/disable the send function in the SPU's or to step 1042 to clear the send function data buffer in the ECU. From steps 1039 or 1042, the program advances respectively to step 1040 or step 1043 and returns to to the main loop as earlier described.

If the COMMAND byte at step 1031 is hex 84-87 (SEND FUNCTION DATA), the program advances to step 1044 where the Data Processor checks the value of the send function data count byte to determine whether or not the ECU has any send function data to return to the CCC. If the ECU has no send function data, the program branches from step 1044 to step 1047 and returns to the main loop as earlier described. Otherwise, the program advances to step 1045 where the ECU's send function data is transmitted to the CCC. The program then advances to step 1046 and returns to the main loop as earlier described.

Finally, if the COMMAND byte at step 1031 is hex 88 (PAY-PER-VIEW), the program branches to step 1048 where the MS tuning data contained in the PAY-PER-VIEW message is stored in the ECU's Program Event Map. The program then advances to step 1049 where the Data Processor checks the Program Authorization Map to determine for a first subscriber whether or not the subscriber has ordered to view the pay-

per-view program. If a subscriber has requested to view the pay-per-view event, the program advances to step 1050 where the SU associated with that subscriber is force tuned to the pay-per-view program, the associated five-minute preview timer is started, the event-order LED on the subscriber's SPU is set to flashing, and the SPU's power relay is activated to turn on the subscriber's television. The program then advances to step 1051 which causes the program to loop back to step 1049 for each of up to six subscribers. After looping for all subscribers, the program from step 1051 advances to step 1052 and returns to the main loop as earlier described.

Operate 2 Routine

If the main routine detects at step 1014 (Figure 18d) that the 100/64-second timer has timed out, the program branches to the Operate 2 routine, shown in Figure 18f. The Operate 2 routine functions to transfer control of the Data Processor to any of a plurality of application programs. As earlier described, application programs implement a variety of functions, such as responding to SPU key presses and implementing the requested operation (e.g., channel selection pay-per-view, parental control), activating the SPU's power relay, activating (flashing or non-flashing) and deactivating the SPU order event LED, clearing the SPU seven-segment display, sending data (e.g., program or channel information) to the SPU display, and so forth.

The Operate 2 program operates as follows. The Data Processor maintains in memory a time table having a pluraliity of two-byte entries for each of up to 8 devices on each of up to 6 different drops associated with the ECU. In one embodiment, the time table has 64 entries (0-63), although in the

described embodiment there may be no more than 6 drops with no more than 8 devices (up to 4 SPUs and up to 4 other devices) on each drop associated with each ECU. The entries in the time table are sequentially arranged by drop and device, such that entries 0-7 are associated with devices having addresses 0-7 on drop 0, entries 8-15 are associated with devices having addresses 0-7 on drop 1, and so on. As previously described, the entries in the time table are set by the various application programs as a time out value prior to a return to the main routine from the application program.

Upon entry into the Operate 2 routine, a time table pointer (I) is set to a value from 0-63 (step 1060) as a function of the value of a time table counter (J). The routine then advances to step 1061, where the I pointer is used to read the Ith entry (associated with a particular device on a particular drop as described above) from the time table. If the value of that entry is hex FFFF (signifying that the timer is off), the routine branches to step 1066 where the time table counter J is incremented by one in preparation for the next pass through the Operate 2 routine. If the entry is other than hex FFFF, the routine advances to step 1062 where the time table entry is decremented by one. If the time table value after decrementing is not equal to zero (step 1063), the routine branches to step 1066 where the J counter is incremented as previously described.

On the other hand, if the timer entry is equal to zero, the timer has timed out and the routine advances to step 1064 where a zero is placed in a memory location (Key Code), and the value of the I pointer is used to interrogate a jump table. The jump table is a table maintained in the ECU's memory which is similar in organization to the time

table. However, the jump table entries specify the memory location in an application program to which the program should jump. These values may point to the start of an application program, or to a point within an application program if the application program had previously returned to the main routine prior to completing the application program's task. Based upon the entry contained in the jump table, the Operate 2 routine then advances to step 1065, where the routine jumps to the point in an application program ("APL") specified by the jump table. When the application program returns to the Operate 2 routine, the Operate 2 routine advances to step 1066 where the J counter is incremented as earlier described. The routine then advances to step 1067 to return to the main loop.

Operate 3 Routine

If the main routine determines at step 1015 (Figure 18d) that the Drop Processor has data for the Data Processor, the program branches to the Operate 3 routine, shown in Figure 18g. The Operate 3 routine functions to appropriately respond to data received from the Drop Processor. Such data may include 84 Commands (Unsolicited Data Responses), and 04 Responses received from associated SPUs.

As shown in Figure 18g, the Operate 3 routine at step 1070 first determines what type of message is being sent from the Drop processor. If the message is an 01, 03, 05, 07 or 08 command response (earlier described), no action is required and the Operate 3 routine advances to step 1083 to return to the main routine as earlier described. Although in the flow chart of Figure 18g no action is taken in response to an 01, 03, 05, 07 or 08 response, it will be apparent to those skilled in the art that various

modifications may readily be made to the program flow to cause the Data Processor to respond to any or all of these command responses. For example, the program may be modified to cause the Data Processor upon detecting in an Ol response that power is not being received from a particular drop to notify the system operator of this fact.

If an 84 Command is detected at step 1070, the Operate 3 program branches to step 1072 to determine if an error has occurred. If "yes", the program branches to step 1073 where a device error counter is incremented in an error operation subroutine. If the counter reaches a predetermined value (e.g., 2), the error subroutine causes a re-initialization of pointers and jump table entries associated with the SPU or device sending the 84 Command. The program then advances to step 1083 to return to the main loop as earlier described. On the other hand, if no error is detected at step 1072, the program advances to (1) step 1074, where the jump table pointer is set, (2) step 1075, where the received data is placed in a memory location (Key Code), and (3) step 1076, where the program jumps via the jump table to the appropriate application program (APL). When the application program returns to the Operate 3 routine, the Operate 3 routine advances to step 1083 and returns to the main loop.

Finally, if an 04 Response is detected at step 1070, the Operate 3 routine advances to step 1071 to check for a transmission error. If an error has occurred, the routine branches to step 1073. Otherwise, the routine advances to step 1077 where the Data Processor determines if the 04 Response is a status response. If the 04 Response is not a status response, the program branches from step 1077 to step 1083 to return to the main loop as earlier

described. Otherwise, the program advances to step 1078. At step 1078, if the status response indicates that a key has been recently depressed on the device keyboard, the routine branches to steps 1080, 1081 and 1082 to respond to the key press as described above with respect to steps 1074-1076. If the status response indicates that no key has been recently depressed, the program advances from step 1078 to step 1079 where the status byte is checked to determine the state of bit 7. As earlier described, bit 7 indicates as a function of the setting of SPU switch 780 (Figure 7) whether the responding device is a master or slave SPU and, thus, to which converter (primary or secondary) the SPU is assigned. After step 1079, the program advances to step 1083 to return to the main loop as earlier described.

Operate 4 Routine

Lastly, if the main routine at step 1016 (Figure 18d) determines that the pay-per-view timer has timed out, the program branches to the Operate 4 routine shown in Figure 18h. This routine starts by entering a loop at step 1091 to determine for each subscriber whether or not the subscriber is viewing a pay-per-view program. If the subscriber is not viewing a pay-per-view program at step 1091, the routine branches to step 1096 where the routine loops back to step 1091 to make the foregoing determination for the next subscriber. If at step 1091 a pay-perview event is being viewed by a subscriber, the routine advances to step 1092 to check the associated 5-bit preview timer in the appropriate byte of the Program Authorization Map. If the value of the byte is greater than or equal to F8, indicating that the byte's five most significant bits (i.e., the timer bits) are all set to "1" and the preview period has

expired, the program branches to step 1096. However, if the value of the byte is less than hex F8, indicating that at least one of bits 3-7 of the byte is equal to zero and the preview period has not expired, then the program advances to step 1093 where the 5-minute timer is incremented by setting a timer bit to "1". The routine then advances to step 1094, where the value of the byte is again checked. If the five timer bits are now all set to "1", then the preview period has expired and the program branches to step 1095 to cause the order-event LED on the subscriber's SPU to glow steadily to indicate that the subscriber will be charged for the pay-per-view event. Otherwise, the program branches to step 1096. Step 1096 causes the routine to loop to setp 1091 to check for each subscriber whether or not a pay-forview event is being viewed. At step 1096, after the routine has determined for each subscriber whether or not the subscriber is reviewing a pay-per-view event, the routine advances to step 1097 and returns to the main loop as earlier described.

F. Polling and Handshaking

In the above-described system, an ECU transmits a message to the CCC only if the ECU receives a CCC message which requires a return message (e.g., READ, ECHO BACK or SEND FUNCTION DATA messages).

Otherwise, ECUs do not transmit messages to the CCC.

Thus, in the above-described system, it is possible for an ECU to have important information to send to the CCC (e.g., information received from a subscriber requesting additional services, or information from a medical monitoring device attached to the drop cable of an ECU), but be unable to notify the CCC of this fact. Also, because ECUs in the above-described system do not ordinarily respond to

the CCC upon receipt of a CCC message, the CCC might not become alerted to an inoperative ECU or transmission link until a message requiring a response (e.g., READ) was addressed to the ECU and the responsive message was not received by the CCC.

To enable ECUs to send important information to the CCC in a timely fashion, and to provide for a check that ECUs are operative, a polling and handshaking communication protocol may be used. In view of the potential for a large number of ECUs (up to 65,536 on each of up to 4 banks) on the cable network of the present invention, an important consideration in designing such a protocol is to minimize the time required to poll and handshake with individual ECUs.

The present invention therefore provides for a handshaking scheme which informs the CCC of inoperative ECUs but which does not require the transmission of relatively lengthy formatted messages. In addition, the present invention provides for a polling scheme which allows an ECU to notify the CCC that the ECU has information for the CCC, but does not require the transmission of lengthy information messages to the CCC in response to the receipt by an ECU of a poll message. The polling scheme enables the CCC to gather information from the ECUs via two independently operating mechanisms. A first or "general" polling scheme allows the CCC to poll each ECU to determine if the ECU has information to send to the CCC. The general polling scheme allows for the detection in less than 20 seconds of all operative ECUs which require service. A second or "priority" polling scheme allows for the detection in less than 20 milliseconds of any one ECU having so-called priority information for the CCC. For both polling schemes, the response "level" is established by the CCC in advance of the poll to identify

and obtain responses from only those ECUs having information falling within a predetermined level or threshold of importance. The level of information may be a function, e.g., of the value or timeliness of the information.

Message Format

The polling and handshaking protocols are described below with respect to an alternative basic message format from that earlier described and shown in Figures 10-11. This alternative basic message format is illustrated in Figures 19-20.

Figure 19 shows an alternative basic message format for data communication in the forward direction (i.e., from the CCC to an ECU). Each message is of a predetermined format, comprising: a FLAG byte, a SEND CONTROL ("SEND CNTL") byte, a plurality of DATA bytes, two CYCLIC REDUNDANCY CHECK ("CRC") bytes, and another FLAG byte. Each byte is comprised of 8 bits. The FLAG and CRC bytes are identical to and serve the same function as the FLAG and CRC bytes previously described.

The SEND CNTL byte in the message of Figure 19 is used to define any of 256 unique commands. As described in greater detail below, SEND CNTL commands may cause an ECU to return information to the CCC, or may cause the ECU to perform a specified operation.

The DATA bytes may comprise from 0 to 255 bytes per message. The SEND CNTL byte specifies how the DATA bytes are to be interpreted by the ECU. If a message is transmitted to a particular ECU, the first two DATA bytes typically specify the ECU address from 0-65536. The first address byte ("ADL") specifies the low-order part of the address, and the second byte ("ADH") specifies the high-order part. Also,

typically, the third DATA byte of a message addressed to a particular ECU is a CONTROL ("CTL") byte. The CTL byte may specify the ECU drop, if any, for which the message is designated, the particular reverse channel that the ECU should use to respond to the CCC, etc.

An alternative basic message format in the reverse direction (i.e., from the ECUs to the CCC) is shown in Figure 20, and is similar to the format for forward communication. Thus, FLAG bytes are used to identify the beginning and end of a message. Following the beginning FLAG byte is a RECEIVE CONTROL ("REC CNTL") byte. The REC CNTL byte, which need not be identical to the SEND CNTL byte, specifies how subsequent DATA bytes, if any, contained in the message are to be interpreted by the CCC. Two CRC bytes, earlier described, follow the last DATA byte.

In addition to the foregoing basic messages, special ECU poll response bytes are utilized. These poll response bytes are comprised of one or two byte-times of carrier from an ECU. As described below, these poll response bytes are used as a handshake in response to polling and informational messages sent from the CCC.

General Level Polling Protocol

The first polling method is the so-called General Level Request ("GLR") poll. This mechanism is used to sequentially address a poll message to each ECU in the system to determine whether or not the ECU requires service (i.e., whether or not the ECU has information for the CCC). Prior to the poll, the CCC establishes the "level" at which the ECUs will respond to the poll. Once the CCC has established the poll level, an ECU responds to a GLR poll only if the ECU (a) requires service, and

(b) has information to transmit to the head end 12 which is at a level equal to or less (i.e., more important) than the level previously established by the CCC. The addressed ECU upon receipt of a GLR poll responds by sending to the CCC one or two General Poll Response ("GPR") bytes. Each GPR byte consists of one byte-time of carrier from the ECU, or "11111111. If the CCC fails to detect a GPR byte from the polled ECU within a predetermined time interval (e.g., 350 microseconds), the CCC presumes the ECU to be inoperative. After a predetermined number of (e.g., five) unsuccessful attempts to contact the ECU, the CCC prints an appropriate error message to the head end operator.

If the addressed ECU transmits to the CCC a single GPR byte in response to a GLR poll, the CCC interprets this to mean that the ECU is operative and does not require servicing. The CCC then polls the ECU having the next sequential address. However, if the ECU returns two GPR bytes, the CCC interprets the response as a service request from an operative ECU. Using the GLR poll, the CCC periodically cycles through all active ECUs and constructs a Service Request table in memory. The CCC subsequently uses this table to selectively retrieve, using a Priority Information Request message later described, information from only those ECUs requiring service. At a forward data transmission rate of 200 Kbps, a complete general poll request cycle of 65,536 ECUs typically takes less than 20 seconds.

The GLR poll is implemented by the CCC as follows. First, the CCC transmits a General Level Request Threshold ("GLRT") message. A typical GLRT message is shown in Figure 21a in accordance with the basic message format of Figure 19. The GLRT message has a SEND CNTL byte equal to 08 and is used

7

by the CCC to establish the response threshold level for the GLR poll, as earlier described. The response threshold is established by a level ("LVL") byte contained within the GLRT message. The first two bits of the CTL byte of the GLRT message specify how the ECU should interpret the LVL byte. If the first two bits of the CTL byte are "01", this is interpreted by the ECU to mean that the ECU should respond positively (i.e., with two GPR bytes) to subsequent poll messages only if the level of the ECU's information is equal to the level set forth in the LVL byte. If the first two CTL byte bits are "10", this means the the ECU should respond positively to poll messages if the level of information to be sent to the CCC is equal to or less than the LVL value.

After sending the GLRT message to establish the poll level, the CCC transmits one or more General Level Request Poll ("GLRP") messages. A typical GLRP message is illustrated in Figure 21b in accordance with the basic message format of Figure 19. As shown in Figure 21b, the SEND CNTL byte of a GLRP message may be any value equal to 0, 1, 2, or 3. The SEND CNTL byte of the message specifies to the addressed ECU that the message is a GLRP message, and further specifies on which reverse channel (0, 1, 2, or 3) the ECU should send GPR response bytes. If an ECU responds to the GLRP message with two GPR bytes on the specified reverse channel, this is interpreted by the CCC as a service request from an operative ECU as earlier described. If one GPR byte is returned, this is interpreted by the CCC as a response from an operative ECU not requiring service. GPR bytes are received, the CCC presumes the ECU to be inoperative.

3. Priority Polling Protocol

The second or priority polling method is the so-called Priority Information Window ("PIW") poll. This second method establishes a priority "window" on the cable network such that any ECU having information to send to the head end which falls within the pre-established priority window will alert the head end of this fact on a predetermined priority service request channel in response to the receipt of any general polling request addressed to any ECU.

Priority polling is enabled by a Priority Information Request Window Control ("PIRWC") message sent from the CCC. The PIRWC message, illustrated in Figure 22a in accordance with the format of Figure 19, is used by the CCC to set the ECU priority response threshold level. As shown in Figure 22a, a PIRWC message has a SEND CNTL byte equal to 9. A LVL byte of the PIRWC message specifies the priority response threshold level. The ECU interprets the LVL byte in a manner determined by the value of the bits in a control ("CTL") byte. Bits 0 and 1 of the CTL byte specify whether the ECU should respond if the level of its information is equal to the value of the LVL byte, or whether the ECU should respond if its level of information is equal to or less than the LVL value. In addition, bit 2 of the CTL byte specifies whether to turn the PIW function in the ECU on or off. Finally, bits 3 and 4 of the CTL byte specify on which of the four reverse channels the ECU should return a priority response. The values and functions of the bits of the CTL byte in one embodiment of the PIRWC message are set forth below:

TABLE E

PIRWC CTL BYTE

<u>B1</u>	<u>B0</u>	<u>Function</u>
0		The ECU should respond to a priority poll only if the level of its information equals the value of LVL.
1	0	The ECU should respond to a priority poll only if the level of its information is equal to or less than the value of LVL.
<u>B2</u>		Function
0		Set PIW in ECU off.
1		Set PIW in ECU on.
<u>B4</u>	<u>B3</u>	Function
0	0	Return priority response on reverse channel 0.
0	1	Return priority response on reverse channel 1.

After a PIRWC message is transmitted to and received by the ECUs, any ECU with priority information corresponding to the threshold level established by the PIRWC message will transmit to the CCC on the specified priority reverse channel a general poll response (GPR) byte after reception of any general level poll message. The reception by the CCC on the priority reverse channel of a GPR byte (there may be more than one response from a plurality of ECUs) alerts the CCC that an ECU (the identity of which is as yet unknown to the CCC) has priority information to send. Upon receipt of such a priority response, the CCC transmits a series of

messages, described below, to disable the priority "window" and to locate within 20 milliseconds an ECU sending the priority poll response.

Assuming for the moment that the CCC has identified an ECU returning a priority response (or requesting service in response to the earlier described GLR poll), the CCC obtains the information from the identified ECU by addressing a Priority Information Request ("PIR") message to the ECU. There are four PIR messages: PIRO, PIRI PIR2, and PIR3, having SEND CNTL bytes equal to 4, 5, 6, and 7 respectively (Figure 22b). The PIRO, PIR1, PIR2 and PIR3 messages cause the ECU to send its priority information to the CCC on reverse channels 0, 1, 2, or 3, respectively.

In response to a PIR message, the addressed ECU transmits its priority information to the CCC using a Priority Information Request Response ("PIRR") message. The PIRR message allows an ECU to send to the CCC any of 256 different messages or values of numeric data for each drop associated with the ECU. A typical PIRR message is illustrated in Figure 22c in accordance with the format of Figure 20.

As shown in Figure 22c, a PIRR message includes a REC CNTL byte equal to 0. A LEVEL ("LVL") byte specifies the threshold level assigned to the priority information which the ECU is transmitting to the CCC (the LVL byte will either match the level previously established, or be numerically less than that level, depending upon the information contained in the previously sent PIRWC message). Following the LVL byte is a CONTROL ("CTL") byte. The CTL byte specifies by the setting of bits 0-5 the drop or drops to which the priority information contained in the message relates. Each bit position 0-5 in the CTL byte is associated with a different ECU drop. For each drop as to which the ECU is sending priority

information, the ECU sets to "1" the corresponding bit in the CTL byte. Following the CTL byte are up to 6 bytes of data (Dn), each byte representing a predetermined or "canned" priority message or numeric value with respect to a different one of the 6 drops associated with the ECU and specified in the CTL byte. The message concludes with the usual CRC and FLAG bytes.

Various divisions and definitions may be used for establishing the different levels of ECU priority information. For example, levels 0-7 may be associated with medical information obtained from medical monitoring devices attached to an ECU drop cable. Similarly, levels 16-23 may be associated with security information obtained from security devices attached to an ECU drop. Lower levels, such as levels 32-39, may be used by an ECU to inform the CCC of syntax or other errors contained in CCC messages received by the ECU. Similarly, information such as ECU status information, subscriber requests for additional services, subscriber responses to interactive two-way services, and other information may be associated with other priority levels.

The manner in which the CCC identifies an unknown ECU responding with a priority service request will now be described.

The CCC identifies an unknown ECU having priority information for the CCC using a binary sort method. The binary sort method involves dividing the population of ECUs having sequential addresses in the range of 0 to n into first and second groups of ECUs having respectively a first group address range from 0 to n/2, and a second group address range from n/2 + 1 to n. The CCC then transmits a message to the first group to determine whether or not any ECUs in the first group have priority information. If the first group includes an ECU (still unknown)

having priority information, the CCC subdivides the first group into third and fourth groups in the manner earlier described, and sends a message directed now to the third group to determine whether or not any ECUs in the third group have priority information to send. If the third group includes an ECU having priority information, the CCC subdivides the third group into fifth and sixth groups and repeats the foregoing process. If the CCC at any time determines that the group (first, third, fifth, etc.) with which it is working does not have priority information, the CCC knows that the other respective group (second, fourth, sixth, etc.) must contain the ECU having the priority information. The CCC then transmits messages to and repetitively subdivides that group until, eventually, the CCC subdivides a group to a single ECU having priority information. As will be apparent to those skilled in the art, the foregoing binary sort method in the case of 65,536 (2¹⁶) ECUs requires no more than 16 iterations to locate an ECU having priority information.

The messages used by the CCC in implementation of the binary sort method in an embodiment of the invention are shown in Figures 23a-d.

The CCC initiates a search for an unknown ECU having priority information using a Binary Sort Initialization ("BSI") message, shown in Figure 23a. The BSI message has a SEND CNTL byte equal to 10, followed by two bytes specifying (in low and high order parts) a binary sort high address ("BSHAL" and "BSHAH") and two bytes specifying (in low and high order parts) a binary sort low address ("BSLAL" and "BSLAH"). The BSI message is sent by the CCC following receipt of a GPR byte on the priority information reverse channel. The BSI message is used by the CCC to turn the priority information window off, to specify the binary sort group high address, and

to specify the binary sort group low address. No response to the BSI message is expected from any ECU.

After the binary sort is initialized with the BSI message, the CCC transmits a series of binary sort poll messages to locate an ECU having priority information to send. Each binary sort poll message turns the priority information window off and specifies a binary sort group address range. Upon receipt of a binary sort poll message, any ECU having priority information within the priority information threshold level and an address within the specified group address range responds by transmitting to the CCC a GPR byte on the priority information channel previously established by the CCC. Three binary sort poll messages, shown in Figures 23b-23d, are utilized in one embodiment of the invention to define the binary sort group range.

Figure 23b shows a Binary Sort Poll High and Low ("BSPHL") message. This message is used by the CCC to specify a binary sort group address range bounded between a low address and a high address. The BSPHL message has a SEND CNTL byte equal to 11. Following the SEND CNTL byte are two bytes specifying the binary sort high address ("BSHAL" and "BSHAH"), and two bytes specifying the binary sort low address ("BSLAL" and "BSLAH"). Any ECU having priority information within the priority information threshold level and having an address within the low and high group address range specified in the BSPHL message responds to the CCC by transmitting a GPR byte on the priority information reverse channel.

Figure 23c shows a Binary Sort Poll Low ("BSPL") message. The BSPL message, having a SEND CNTL byte equal to 12, is similar to the BSPHL message except that the BSPL message specifies only a binary sort low group address ("BSLAL" and "BSLAH"). This

message is used by the CCC to subdivide a group address range by modifying only the low address of the group range. The BSPL thus enables the CCC to subdivide a group address range without having to send both the low and high addresses of the range. Any ECU having priority information within the priority information threshold level and having an address which is greater than or equal to the specified group low address of the BSPL message and less than or equal to the previously specified high group address responds to the CCC by transmitting a GPR byte on the priority information reverse channel.

Finally, Figure 23d shows a Binary Sort
Poll High ("BSPH") message. The BSPH message includes
a SEND CNTL byte equal to 13. In this message, two
bytes specify a binary sort group high address
("BSHAL" and "BSHAH"). This message is used similarly
to the BSPL message to subdivide a group by modifying
only one (i.e., the high) group address. Any ECU
having priority information within the priority information threshold level and having an address which
is less than or equal to the group high address of
the BSPH message and greater than or equal to the
previously specified low group address responds to
the CCC by transmitting a GPR byte on the priority
information reverse channel.

4. Information Protocol

When information, rather than a poll or status request, is transmitted from the CCC to an ECU, an informational protocol including a handshaking sequence is used to provide the CCC with positive feedback that (a) the ECU received the message, (b) the message syntax was proper, (c) there were no transmission errors, and (d) the ECUs are operative. The handshaking sequence does not require the trans-

mission of lengthy formatted messages, thus minimizing the amount of time required to handshake with the CCC.

The handshaking response to informational messages is a General Poll Response Verification ("GPRV"), comprising one or two bytes of "11111111". If no GPRV is detected by the CCC, the CCC interprets this to mean that the ECU is inoperative. If a single byte is received, the CCC interprets this to mean that the message was not accepted by the ECU. If two bytes are received, the CCC interprets this to mean that the message was received by the ECU without error and that processing will occur. If a two-byte response is not received, the CCC will try a predetermined number of times (e.g., five) before logging and notifying the operator of an error.

While preferred embodiments of the invention have been set forth for purposes of the disclosure, modification to the disclosed embodiments may occur to those skilled in the art. Accordingly, the appended claims are intended to cover all embodiments of the invention and modifications to the disclosed embodiments which do not depart from the spirit and scope of the invention.

What Is Claimed Is:

1. A cable television system for providing selected television signals to a plurality of remotely located subscriber premises, having a head end for producing a television signal and a cable network for conducting the television signal from the head end to a plurality of remote locations, each of which is adjacent but external to a respective subset of the subscriber premises, comprising:

external control unit means at each of the remote locations for receiving the television signal from the cable network;

a plurality of drop cables connected to each external control unit means, each drop cable conducting a selected portion of the television signal from the external control unit means to a respective one of the subscriber premises associated with that external control unit means;

subscriber device means connected to each drop cable at the subscriber premises for applying to the drop cable a first control signal indicative of data to be transmitted to the external control unit means, at least one of said subscriber device means being a subscriber processing unit means for allowing the subscriber to apply to the drop cable a first control signal including channel data indicative of the portion of the television signal which that subscriber wishes to select; and

first means associated with each external control unit means for processing the first control signals applied to all the drop cables associated with that external control unit means and for causing that external control unit means to apply to each associated drop cable the portion of the television signal indicated by the first control signal

channel data received via the drop cable, the first means including common signal processing circuitry which at least partially processes the information represented by the first control signals applied to all of the drop cables associated with that external control unit means.

2. The apparatus defined in claim 1, further comprising:

second means associated with each external control unit means for applying to each drop cable a second control signal indicative of data to be transmitted to the associated subscriber premises; and

third means associated with each subscriber processing unit means for processing the second control signal to receive and store the data indicated by the second control signal.

3. The apparatus defined in claim 2, wherein: said subscriber processing unit means includes a character display means;

the second control signal applied to each drop cable includes character display data; and said subscriber processing unit means includes fourth means responsive to the received and stored second control signal for controlling the character display means in accordance with the character display data indicated by the second control signal.

4. The apparatus defined in claim 3, wherein the character display data indicated by the second control signal applied to each drop cable are indicative of the selected portion of the television signal applied to that drop cable by the external control unit means.

5. The apparatus defined in claim 2, further comprising:

fourth means associated with the head end for applying to the cable network a third control signal indicative of data to be transmitted to at least one external control unit means; and

fifth means associated with each external control unit means for processing the third control signal to receive and store the data indicated by the third control signal.

6. The apparatus defined in claim 2, further comprising:

sixth means associated with each external control unit means for applying to the cable network a fourth control signal indicative of data to be transmitted to the head end; and

seventh means associated with the head end for processing the fourth control signal to receive and store the data indicated by the fourth control signal.

7. The apparatus defined in claim 5, further comprising:

sixth means associated with each external control unit means for applying to the cable network a fourth control signal indicative of data to be transmitted to the head end; and

seventh means associated with the head end for processing the fourth control signal to receive and store the data indicated by the fourth control signal.

8. The apparatus defined in claim 5, wherein:

said fifth means associated with each external control unit means includes eighth means for producing address signal information which uniquely identifies the associated external control unit means;

the third control signal includes address signal data indicative of at least one external control unit means to which the third control signal is to be transmitted; and

said fifth means associated with each external control unit means includes ninth means for comparing the received address signal data to the associated address signal information, and enabling the associated fifth means to store the data indicated by the third control signal if the received address signal data bear a predetermined relationship to the associated address signal information.

- 9. The apparatus defined in claim 8, wherein said ninth means associated with each external control unit means enables said fifth means to store the data indicated by the third control signal if the received address signal data correspond to the associated address signal information.
- 10. The apparatus defined in claim 5, wherein:

the third control signal includes broadcast address signal data indicative of all external control unit means; and

said fifth means associated with each external control unit means includes tenth means for recognizing the broadcast address signal data, and enabling the associated fifth means to store the data indicated by the third control signal if the received broadcast address signal data is recognized.

0167237

11. The apparatus defined in claim 5, wherein:

the third control signal includes channel authorization data indicative of the portions of the television signal which at least one subscriber associated with that external control unit means is authorized to select; and

said fifth means associated with each external control unit means includes eleventh means for causing said external control unit means to apply to each associated drop cable the portion of the television signal indicated by the first control signal channel data received via the drop cable only if the stored channel authorization data indicates that the subscriber associated with the drop cable is authorized to receive that portion of the television signal.

12. The apparatus defined in claim 5, wherein:

the third control signal includes channelization data indicative of a desired correlation between each portion of the television signal which can be selected by the subscriber and the channel data indicated by the first control signal used to select each portion of the television signal; and

said fifth means associated with each external control unit means includes twelfth means responsive to the channelization data for causing the external control unit means to apply to each associated drop cable the correlated portion of the television signal indicated by the first control signal channel data received via the drop cable.

13. The apparatus defined in claim 5, wherein: the third control signal includes force tune data indicative of a portion of the television signal for transmission to the subscriber premises; and

said fifth means associated with each external control unit means includes thirteenth means responsive to the force tune data for causing said external control unit means to apply to the associated drop cables the portion of the television signal indicated by the force tune data.

14. The apparatus defined in claim 13, wherein:

said second means associated with each external control unit means includes fourteenth means responsive to the force tune data for causing said second means to apply to the associated drop cables the second control signal;

the second control signal applied to each drop cable includes television on/off data; and said subscriber processing unit means includes fifteenth means responsive to the second control signal for controlling on and off a television apparatus in accordance with the television on/off data.

15. The apparatus defined in claim 8, wherein: said fifth means associated with each external control unit means includes sixteenth means for storing data at one or more storage addresses;

the third control signal includes storage address data indicative of a storage address in said external control unit means; and

said fifth means associated with each external control unit means includes seventeenth means for causing said associated sixteenth means to store the data indicated by the second control signal

commencing at a storage address which bears a predetermined relationship to the storage address data indicated by the third control signal.

16. The apparatus defined in claim 6, wherein: the first control signal includes data indicative of information to be transmitted from a subscriber device means to the head end;

said first means associated with each external control unit means includes eighteenth means to receive and store the information indicated by the first control signal;

the third control signal includes read data indicative of a request to transmit to the head end the information stored in said eighteenth means; and

said sixth means associated with said external control unit means includes nineteenth means responsive to the third control signal for enabling said sixth means to apply to the cable network the fourth control signal including data indicative of the stored information.

17. The apparatus defined in claim 6, wherein:

the first control signal includes data indicative of information to be transmitted to the head end;

said first means associated with each external control unit means includes twentieth means to accumulate and store the information indicated by the first control signals applied to all of the drop cables associated with that external control unit means;

the third control signal includes send function data indicative of a request to transmit to the head end the accumulated information stored in said twentieth means; and

said sixth means associated with said external control unit means includes twenty-first means responsive to the send function data of the third control signal for enabling said sixth means to apply to the cable network the fourth control signal including data indicative of the accumulated and stored information.

18. The apparatus of claim 5, wherein:
the first control signal includes
data indicative of a request to view a pay-per-view
program event;

the third control signal includes pay-per-view program event data indicative of the transmission of a pay-per-view program event and the portion of the television signal corresponding to that pay-per-view program event; and

external control unit means includes twenty-second means responsive to the pay-per-view program event data of the third control signal for applying to each associated drop cable the portion of the television signal indicated by the third control signal if the pay-per-view program event indicated by the third control signal indicated by the third control signal corresponds to the pay-per-view program event request of the first control signal.

mitting via a cable network television signals from a head end to a plurality of remote locations, and other signals between the head end and the plurality of remote locations, comprising:

means at each of the remote locations for receiving the television signals from the cable network;

first means associated with the head end for applying to the cable network a first control signal indicative of data to be transmitted to at least one receiving means, at least a portion of the first control signal being indicative of a particular one of a plurality of reverse channel frequency bands; and

second means associated with each receiving means for processing the first control signal and for applying to the cable network in any one of a plurality of reverse channel frequency bands a second control signal indicative of data to be transmitted to the head end, said second means being responsive to the first control signal for applying the second control signal in the reverse channel frequency band indicated by the first control signal.

20. The cable television system defined in claim 19, wherein each remote location is adjacent but external to a respective set of subscriber premises and wherein said receiving means comprises an external control unit means, said cable television system further comprising:

a plurality of drop cables connected to each external control unit means, each drop cable conducting a selected portion of the television signal from the external control unit means to a respective one of the subscriber premises associated with that external control unit means;

subscriber processing unit means connected to the drop cable at at least one of the subscriber premises for allowing the subscriber to apply to the drop cable a third control signal indicative of the portion of the television signal which that subscriber wishes to select; and

processing means associated with each external control unit for processing the third control signals applied to all of the drop cables associated with that external control unit and for causing that external control unit means to apply to each associated drop cable the portion of the television signal indicated by the third control signals, the processing means including common signal processing circuitry which at least partially processes the information represented by the third control signals applied to all of the drop cables associated with that external control circuit means.

21. A cable television system for transmitting via a cable network television signals from
a head end to a plurality of remote locations, and
other signals between the head end and the plurality
of remote locations, each remote location being
adjacent but external to a set of subscriber premises,
comprising:

addressable external control unit means at each of the remote locations for receiving the television signal from the cable network;

a plurality of drop cables connected to each external control unit means, each drop cable conducting a selected portion of the television signal from the external control unit means to a respective one of the subscriber premises associated with that external control unit means;

subscriber processing unit means connected to each drop cable at the subscriber's premises for allowing the subscriber to apply to the drop cable a first control signal indicative of the portion of the television signal which that subscriber wishes to select;

first means associated with each external control unit means for processing the first control signals applied to all of the drop cables associated with that external control unit means and for causing that external control unit means to apply to each associated drop cable the portion of the television signal indicated by the first control signal received via that drop cable, the first means including common signal processing circuitry which at least partially processes the information represented by the first control signals applied to all of the drop cables associated with that external control unit means;

second means associated with the head end means for applying to the cable network a second control signal indicative of data to be transmitted to at least one external control unit means, wherein at least a portion of the second control signal is indicative of an external control unit means address;

third means associated with each external control unit means for processing the second control signal to receive and store the data indicated by the second control signal if the second control signal is addressed to the external control unit means; and

handshaking means associated with each external control unit means and responsive to the third means to apply to the cable network for transmission to the head end a response signal indicative of whether or not the external control unit means received the second control signal without error.

22. A cable television system for transmitting via a cable network television signals from a head end to a plurality of subscriber premises,

and other signals between the head end and the plurality of subscriber premises, comprising:

polling signal means associated with the head end for applying polling signals to the cable network;

external control unit means located at a plurality of remote locations, each location being adjacent but external to a subset of the subscriber premises, for receiving the television signals and the polling signals from the cable network;

a plurality of drop cables connected to each external control unit means for conducting selected portions of the television signals from the external control unit means to a respective one of the subscriber premises associated with that external control unit means;

subscriber processing unit means connected to each drop cable at the subscriber premises for allowing the subscriber to apply to the drop cable a control signal indicative of information to be transmitted to said external control unit means, including information indicating the portion of the television signal which that subscriber wishes to select and information for transmission to the head end;

control signal processing means associated with the external control unit for receiving and storing the information indicated by the control signals applied to all of the drop cables associated with that external control unit means and for applying to each drop cable the portion of the television signal indicated by the television signal selection information received via that drop cable; and polling signal processing means associated with each external control unit means for processing the received polling signals and for responding thereto by applying a response signal to the cable network for transmission to the head end indicative of whether or not said external control unit means has information to transmit to the head end.

23. The cable television system defined in claim 22, wherein the polling signals include address signal data indicative of the external control unit means to which the polling signal is to be transmitted, and wherein the polling signal processing means further comprises:

means for producing address signal information which uniquely identifies the associated external control unit means; and

means for comparing the received address signal data to the associated address signal information and for causing the polling signal processing means to respond to the received polling signal if the received address signal data bear a predetermined relationship to the associated address signal information.

24. The cable television system defined in claim 23, wherein:

said external control unit means includes means for associating a level of importance with the information which the external control unit means has to transmit to the head end:

said polling signal means associated with the head end includes means for applying to the cable network response threshold level signal data indicative of the level at which said external

control unit means should respond to received polling signals; and

associated with each external control unit means includes means for comparing the received threshold level signal data to the level of the information which the external control unit means has to transmit to the head end, and for enabling the associated polling signal processing means to transmit a response signal to the head end indicating that the external control unit means has information to transmit to the head end if the level of information which said external control unit means has to transmit to the head end bears a predetermined relationship to the received response threshold level signal data.

25. The cable television system defined in claim 23, wherein:

said external control unit means includes means for associating a level of importance with the information which the external control unit means has to transmit to the head end;

with the head end includes means for applying a signal to the cable network for establishing a priority information window on the cable network, the priority information window signal including priority response threshold level signal data indicative of the priority information level at which said external control unit means should respond to the polling signals; and

said external control unit means includes means for receiving the priority information window signal and storing the priority response threshold level signal data, for comparing the priority response threshold level signal data to

the level of information which the external control unit means has to transmit to the head end, and for causing said polling signal processing means associated with said external control unit means to respond to any received polling signal whenever the information which the external control unit means has to transmit to the head end bears a predetermined relationship to the priority response threshold level signal data.

26. A two-way cable television system for transmitting television and other signals via a cable network from a head end to addressable terminal devices at a plurality of remote locations, comprising:

first means associated with the head end for transmitting polling signals to the addressable terminal devices, the polling signals including a terminal device address;

second means associated with the terminal devices for storing information and for assigning a level of importance to the stored information:

third means associated with the head end for transmitting to the terminal devices threshold level control signals indicative of the threshold level at which the terminal devices should transmit information to the head end;

fourth means associated with each terminal devices for receiving the threshold level control signals and for comparing the level of the information stored in the terminal device with the threshold level indicated by the threshold level control signals; and

fifth means responsive to said fourth means and to received polling signals addressed to

the terminal device for transmitting to the head end a response signal indicating that the terminal device has information to transmit to the head end if the level of the information bears a predetermined relationship to the threshold level indicated by the threshold level control signals.

27. A two-way cable television system for transmitting television signals and other signals via a cable network from a head end to addressable terminal devices at a plurality of remote locations, comprising:

first means associated with the head end for transmitting polling signals to the addressable terminal devices, the polling signals including a terminal device address;

second means associated with the terminal devices for storing information and for assigning a level of importance to the stored information;

third means associated with the head end for transmitting to the terminal devices priority information control signals indicative of the priority threshold level at which the terminal devices should transmit information to the head end;

fourth means associated with each terminal device for receiving the priority information control signals and for comparing the level of the information stored in the terminal device with the priority threshold level indicated by the priority information control signals; and

fifth means responsive to said fourth means and to any received polling signal for transmitting to the head end a response signal indicating that the terminal device has information to transmit to the head end if the level of the information bears

a predetermined relationship to the priority threshold level indicated by the priority information control signals.

28. The cable television of claim 27, wherein:

the priority information control signals include data indicative of a particular one of a plurality of reverse channels available for transmission of information from the terminal devices to the head end; and

the terminal devices include sixth means responsive to the priority information control signals for transmitting the response signal in the particular reverse channel indicated by the priority information control signal data.

29. A cable television system for transmitting television signals via a cable network from a head end to a plurality of remote locations, each remote location being adjacent but external to a selected set of subscriber premises, comprising:

external control unit means at each of the remote locations for receiving the television signals from the cable network;

a plurality of drop cables connected to at least one external control unit means, each drop cable conducting a selected portion of the television signal from the external control unit means to a respective one of the subscriber premises associated with that external control unit means;

subscriber device means connected to the drop cable at the subscriber premises for applying to the drop cable a service request signal indicative of a request by the subscriber device means to communicate with the external control unit means; and drop polling means associated with the external control unit means for sensing in a predetermined order on each drop cable of the presence of the service request signal to enable the associated external control unit means to rapidly locate a drop cable on which a subscriber device means is requesting to communicate with the external control unit means.

- 30. The cable television system of claim 29, wherein said drop polling means includes a multiplexer means to selectively connect said drop polling means to each drop cable connected to the external control unit means.
- 31. The cable television system of claim 29, further comprising:

device polling means associated with the external control unit means, said device polling means being responsive to the drop polling means sensing the service request signal on a drop cable for applying a first control signal to that drop cable, the first control signal including data indicative of a subscriber device means address;

address means associated with each subscriber device means for producing address signal information which uniquely identifies the subscriber device means on the drop cable to which the subscriber device means is connected;

transmitter means associated with each subscriber device means for applying to its associated drop cable a second control signal indicative of data to be transmitted to the external control unit means; and

means associated with each subscriber device means for receiving the first control signal, for comparing the received address signal data to

the associated address signal information, and for enabling said transmitter means associated with said subscriber device means to transmit the second control signal if the received address signal data bear a predetermined relationship to the associated address signal information.

32. The cable television system of claim 31, wherein:

a plurality of subscriber device
means are connected to the same drop cable; and
the device polling means includes
means for applying to that drop cable in a predetermined order a plurality of first control
signals, each first control signal including address
data indicative of a different one of the subscriber
devices connected to that drop cable.

- 33. The cable television system of claim 32, wherein at least one of the subscriber device means is a subscriber processing unit means for allowing the subscriber to apply to the drop cable and communicate to the external control unit means second control signals indicative of the portion of the television signal which that subscriber wishes to select.
- 34. A cable television system for providing selected television signals to a plurality of remotely located subscriber premises via a cable network, comprising:

head end means for transmitting a television signal to a plurality of remote locations, each of which is adjacent but external to a respective subset of the subscriber premises;

external control unit means connected to the cable network at each of the remote locations

for receiving the television signal said external control unit means including a slave cable terminal to which the television signal received from the cable network is applied;

a plurality of drop cables connected to each external control unit means, each drop cable conducting a selected portion of the television signal from the external control unit means to a respective one of the subscriber premises associated with that external control unit means;

subscriber processing unit means connected to each drop cable at the subscriber's premises for allowing the subscriber to apply to the drop cable a first control signal indicative of the portion of the television signal which that subscriber wishes to select;

external control unit means for processing the first control signals applied to all the drop cables associated with that external control unit means and for causing that external control unit means to apply to each associated drop cable the portion of the television signal indicated by the first control signal received via that drop cable, the first means including common signal processing circuitry which at least partially processes the information represented by the first control signals applied to all of the drop cables associated with that external control unit means; and

slave external control unit means connected to the slave cable terminal of one of said external control unit means for supplying selected portions of the television signal to additional subscriber processing unit means associated with said slave external control unit means.

35. A cable television system for providing selected television signals to a plurality of remotely located subscriber premises via a cable network, comprising:

head end means for transmitting a television signal to a plurality of remote locations, each of which is adjacent but external to a respective subset of the subscriber premises;

external control unit means at each of the remote locations for receiving the television signal from the cable network;

a plurality of drop cables connected to each external control unit means, each drop cable conducting a selected portion of the television signal from the external control unit means to a respective one of the subscriber premises associated with that external control unit means;

subscriber processing unit means connected to each drop cable at the subscriber's premises for allowing the subscriber to apply to the drop cable a first control signal indicative of a first portion of the television signal which that subscriber wishes to select;

slave subscriber processor unit means connected to the drop cable at at least one subscriber's premises for allowing the subscriber to apply to the drop cable a second control signal indicative of a second portion of the television signal which that subscriber wishes to select; and

means associated with each external control unit means for processing the first and second control signals applied to the drop cables associated with that external control unit means and for causing that external control unit means to apply to each associated drop cable in a first predetermined channel the portion of the television signal indicated by the first control signals received via

that drop cable, and to apply to the drop cable associated with the slave subscriber processing unit means in a second predetermined channel the portion of the television signal indicated by the second control signal received via that drop cable, the first means including common signal processing circuitry which at least partially processes the information represented by the first and second control signals applied to all of the drop cables associated with that external control unit means.

36. A cable television system for providing selected television signals to a plurality of remotely located subscriber premises, comprising:

head end means for transmitting a television signal;

a cable network having a plurality of cables connected in parallel, each cable conducting a different part of the television signal from the head end means to a plurality of remote locations, each of which is adjacent but external to a respective subset of the subscriber premises;

external control unit means at each of the remote locations connected to each of the plurality of cables for receiving the television signal from the cable network;

a plurality of subscriber unit means associated with each external control unit means, each subscriber unit means connected to a drop cable for providing a selected portion of the television signal from the external control unit means to a respective one of the subscriber premises associated with that external control unit means;

subscriber processing unit means connected to each drop cable at the subscriber premises for allowing the subscriber to apply to the drop cable a control signal indicative of the portion of the television signal which that subscriber wishes to select;

cable selecting means associated with each subscriber unit means for selectively connecting each subscriber unit means to one of the plurality of cables of the cable network;

first means associated with each external control unit means for processing the first control signals applied to all the drop cables associated with that external control unit means and for causing each subscriber unit means to apply to each associated drop cable the portion of the television signal indicated by the first control signal received via that drop cable, the processing means including common signal processing circuitry which at least partially processes the information represented by the first control signals applied to all of the drop cables associated with that external control unit means; and

second means responsive to the first means for causing each cable selecting means to connect its associated subscriber unit means to the cable conducting the part of the television signal which includes the portion of the television signal indicated by the first control signal received via the associated drop cable.

37. A cable television system for providing selected television signals to a plurality of remotely located subscriber premises via a cable network, the cable network including a frequency band for reverse communication to the head end, comprising:

head end means for transmitting a television signal to a plurality of remote locations, each of which is adjacent but external to a respective subset of the subscriber premises; ŝ

external control unit means at each of the remote locations for receiving the television signal from the cable network;

a plurality of drop cables connected to each external control unit means, each drop cable conducting a selected portion of the television signal from the external control unit means to a respective one of the subscriber premises associated with that external control unit means;

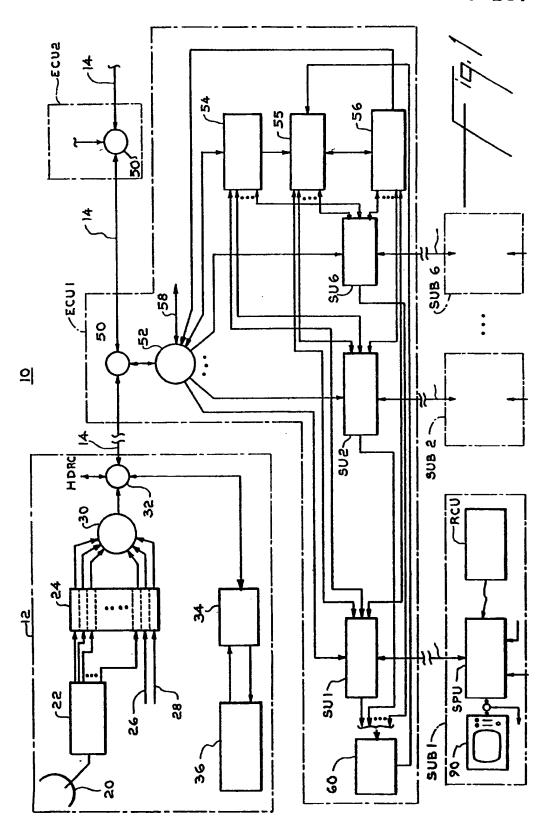

subscriber processing unit means connected to each drop cable at the subscriber premises for allowing the subscriber to apply to the drop cable a first control signal including data indicative of the portion of the television signal which that subscriber wishes to select and subscriber data for transmission to the head end;

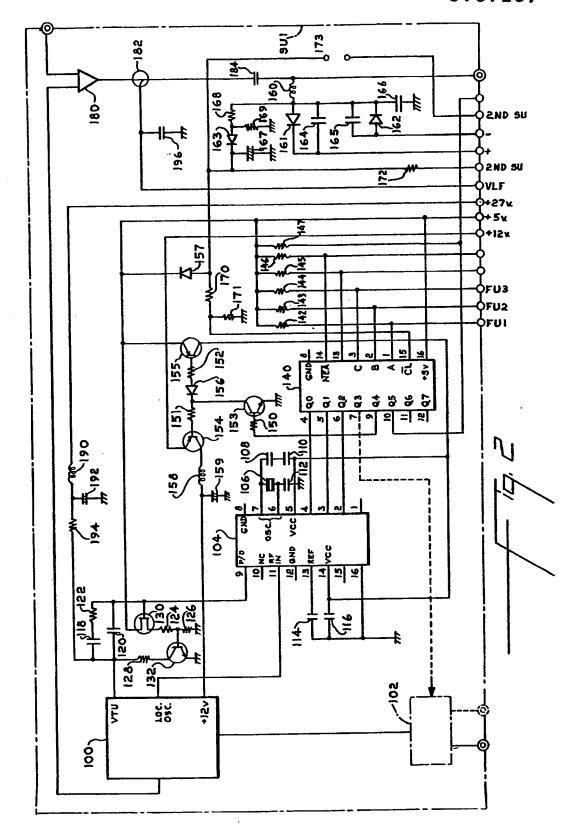

external control unit means for processing the first control signals applied to all the drop cables associated with that external control unit means and for causing that external control unit means to apply to each associated drop cable the portion of the television signal indicated by the first control signal received via that drop cable, and to transmit to the head end signals including the subscriber data indicated by the first control signal, said first means including common signal processing circuitry which at least partially processes the information represented by the first control signals applied to all of the drop cables associated with that external control unit means;

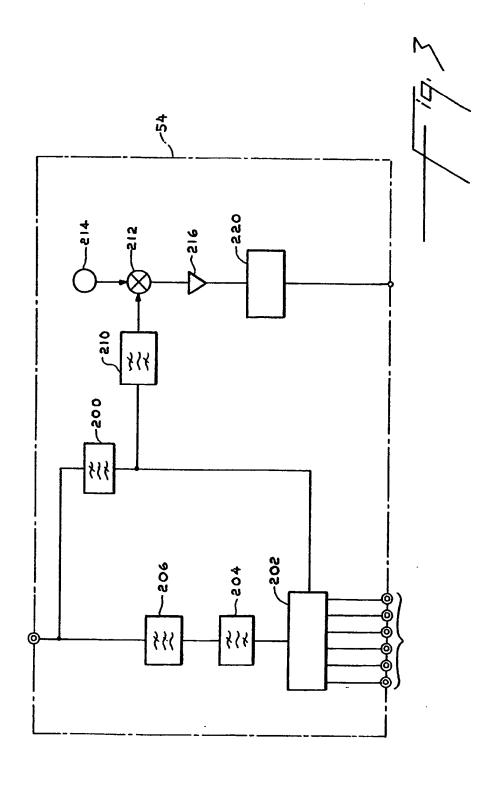

second means connected to each drop cable at the subscriber premises for allowing the subscriber to apply to the drop cable a second control signal including data to be transmitted from the subscriber premises to the head end; and

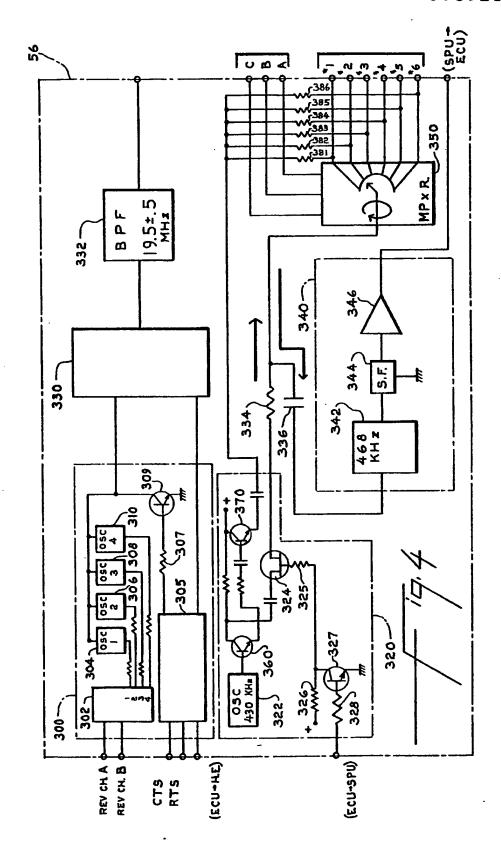

third means associated with each external control unit means and connected to each drop cable and to the cable network for allowing the second control signal to pass through the external control unit means and directly to the head end in a frequency band comprising a portion of the total frequency band available on the cable network for reverse communication so that ingress onto the cable network from the drop cables of signals interfering with the transmitted subscriber data signals is minimized.

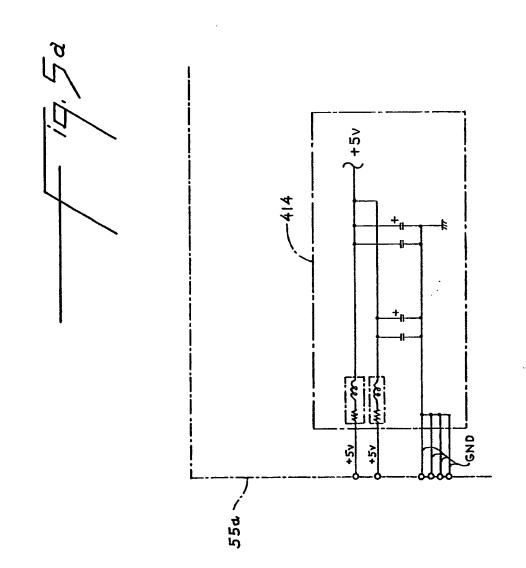

38. The apparatus of claim 37, wherein said third means comprises a bandpass filter.
